IN THE U.S. PATENT AND TRADEMARK OFFICE

Applicant: HIRAMATSU, Tsuyoshi et al. Conf.:  
Int'l. Appl. No.: PCT/JP00/03812  
Appl. No.: New Group:  
Filed: September 19, 2001 Examiner:  
For: PRESSURE SENSITIVE ADHESIVE SHEETS  
FOR REMOVAL OF SOLVENT-CONTAINING  
SUBSTANCES

PRELIMINARY AMENDMENT

**BOX PATENT APPLICATION**

Assistant Commissioner for Patents  
Washington, DC 20231

September 19, 2001

Sir:

The following Preliminary Amendments and Remarks are respectfully submitted in connection with the above-identified application.

AMENDMENTS

IN THE SPECIFICATION:

Please amend the specification as follows:

Before line 1, insert --This application is the national phase under 35 U.S.C. § 371 of PCT International Application No. PCT/JP00/03812 which has an International filing date of June 13, 2000, which designated the United States of America and was not published in English.--

IN THE CLAIMS:

Please amend the claims as follows:

9. (Amended) The pressure-sensitive adhesive sheet for removal of a solvent-containing substance according to claim 1, wherein the pressure-sensitive adhesive sheet is for use in cleaning of a screen printing plate.

REMARKS

The specification has been amended to provide a cross-reference to the previously filed International Application.

The claims have also been amended to delete improper multiple dependencies.

Entry of the above amendments is earnestly solicited. An early and favorable first action on the merits is earnestly solicited.

If necessary, the Commissioner is hereby authorized in this, concurrent, and future replies, to charge payment or credit any overpayment to Deposit Account No. 02-2448 for any additional fees required under 37 C.F.R. § 1.16 or under 37 C.F.R. § 1.17; particularly, extension of time fees.

Respectfully submitted,

BIRCH, STEWART, KOLASCH & BIRCH, LLP

By   
Gerald M. Murphy, Jr., #28,977

Attachment: VERSION WITH MARKINGS TO SHOW CHANGES MADE

VERSION WITH MARKINGS TO SHOW CHANGES MADE

The specification has been amended to provide a cross-reference to the previously filed International Application.

IN THE CLAIMS:

The claims have been amended as follows:

9. (Amended) The pressure-sensitive adhesive sheet for removal of a solvent-containing substance according to [any of claims 1 to 8] claim 1, wherein the pressure-sensitive adhesive sheet is for use in cleaning of a screen printing plate.

(Rev. 8/15/01)

## DESCRIPTION

PRESSURE SENSITIVE ADHESIVE SHEETS FOR REMOVAL OF  
SOLVENT-CONTAINING SUBSTANCES

5

## Technical Field

The present invention relates to sheets for removal of a solvent-containing substance (material) and to methods for removing a solvent-containing substance (material). Such solvent-containing substances include pastes (inks) turned about backs of screen printing plates during screen printing operation, inks deposited on rollers of printing machines for offset printing, gravure printing or flexographic printing, as well as inks for ink-jet printers and paints.

10

## Background Art

Solvent-containing substances such as pastes, inks, and other semisolid substances containing solvents and being in wet conditions are widely used in the fields of printing, 20 paints, and adhesives. However, when these solvent-containing substances are in existence in excess in a specific region or are in existence in an undesired region, they stain or contaminate machinery, equipment or hands, deteriorate the qualities of products and invite other various 25 problems.

For example, when a certain number of printing operations is performed in screen printing, a paste (an ink) turns about the back of a screen printing plate to thereby stain a printed matter or to thereby stain a print image. Thus, precise and

5 beautiful printing cannot be performed. Known methods for removing a paste deposited on a screen printing plate include a method in which the paste is mechanically scraped off using a squeegee, a method in which the paste is wiped off using a wiping rag (waste) and a method in which the screen printing

10 plate is immersed and cleaned in a solvent in a cleaning tank. Known methods for cleaning floors, desks and walls carrying, for example, a deposited fluorescent agent or paint containing a solvent include a method in which the deposit is wiped off using a wiping rag, and a method in which the deposit is scraped off with a spatula or squeegee. However, such methods for

15 cleaning machines or floors carrying deposited solvent-containing substances using a squeegee or wiping rag may damage an article to be cleaned due to physical forces applied on the article and may highly possibly broaden stained

20 portions toward surroundings.

To avoid, for example, bleeding during screen printing, several methods have been proposed in which a paste turned about the back of a printing plate is removed by the use of a pressure-sensitive adhesive sheet. For example, Japanese

25 Unexamined Patent Application Publication No. 3-74893

discloses a method for screen printing of a printed-wiring board in which a paste turned about the back of a printing plate is removed by subjecting the back of the printing plate to screen printing on a pressure-sensitive adhesive side of a

- 5 pressure-sensitive adhesive sheet. Likewise, Japanese Unexamined Patent Application Publication No. 6-297681 describes a method for removing a paste turned about the back of a printing plate in which a pressure-sensitive adhesive sheet is stuck to and peeled off from the printing plate. The publication mentions that the method is not affected by dirt or dust derived from wiping rags or paper to thereby avoid imperfect printing as compared with a method, in which the paste is wiped off with a wiping rag or paper using a solvent. However, the aforementioned publications substantially lack the description about pressure-sensitive adhesive sheets for use in removal of the paste turned about, and Japanese Unexamined Patent Application Publication No. 3-74893 only describes the thickness and tackiness of an appropriate film. Japanese Unexamined Patent Application Publication No.
- 10 20 59-114055 discloses a method for removing an ink remained on a blanket cylinder of an offset printing machine, in which pressure-sensitive adhesive tape is used, but this publication fails to describe any required characteristics of the pressure-sensitive adhesive tape.

25 The present inventors therefore made attempts to remove

pastes or inks by actually using pressure-sensitive adhesive sheets, but expected effects could not be obtained in any of conventionally used pressure-sensitive adhesive tapes or sheets. For example, when a pressure-sensitive adhesive

5 sheet was used, part of the paste was stuck to a pressure-sensitive adhesive surface of the sheet but the remainder of the paste remained on the back of a screen printing plate, and the paste seemed to undergo cohesive failure between screen printing plate and the

10 pressure-sensitive adhesive sheet. When another pressure-sensitive adhesive sheet was used, a pressure-sensitive adhesive layer absorbed a solvent in a paste and lost its tackiness, and a residue (a glop) of the paste after the absorption of the solvent was fixed to the back of the screen printing plate. Additionally, when a highly

15 tacky pressure-sensitive adhesive sheet was used, the pressure-sensitive adhesive sheet could remove the paste but could not be significantly peeled off from the screen printing plate due to its excessively high tackiness and an emulsion 20 of the screen printing plate was peeled off from the printing plate.

Additionally, the present inventors found that, when a conventionally used pressure-sensitive adhesive tape or sheets was used, components derived from the 25 pressure-sensitive adhesive tape or sheet migrated to, for

example, screen printing plate after the pressure-sensitive adhesive tape or sheet was peeled off to thereby stain a surface of the screen printing plate. Such stain causes problems of an article to be treated. For example, when a 5 fluorescent material is screen-printed on a plasma display, the stain of the fluorescent material markedly deteriorate light-emitting characteristics of the fluorescent material.

If an inappropriate pressure-sensitive adhesive tape is used for removal of a solvent-containing substance by sticking 10 the pressure-sensitive adhesive tape to the solvent-containing substance, stains are contrarily broadened. However, according to conventional techniques, several types of such conventional pressure-sensitive adhesive tapes must be actually subjected to testing before 15 selecting an appropriate pressure-sensitive adhesive tape that can clean a target article to be cleaned.

Separately, static electricity builds up during removal of a solvent-containing substance such as a paste with the use of a pressure-sensitive adhesive sheet and invites problems.

20 When two plies of pressure-sensitive adhesive sheets are electrostatically charged and approach each other on a pass line, the pressure-sensitive adhesive sheets are attracted or repel each other due to the static electricity. Additionally, when the pressure-sensitive adhesive sheet is brought close 25 to a screen printing plate carrying a deposited paste (an ink),

the static electricity makes the paste (ink) blown off in some cases. If an operator touches the pressure-sensitive adhesive sheet during operation, he (she) may feel discomfort caused by electrostatic shock. Furthermore, the static 5 electricity may make surrounding dirt or dust deposited on the pressure-sensitive adhesive sheet, thus inhibiting the removal of the paste (ink).

As a possible solution to these problems, a static eliminator is provided in a cleaning unit for a screen printing machine. However, a multitude of static eliminators must be provided in order to inhibit electrostatic buildup in every region of the screen printing machine, thus increasing demerit 10 in cost. Additionally, if the type of a pressure-sensitive adhesive sheet or another means to remove the paste is changed, the region where the static electricity is accumulated changes 15 and an extra static eliminator must be added to the cleaning unit in some cases.

#### Disclosure of Invention

Accordingly, an object of the present invention is to 20 provide a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which can reliably adhere to and remove the solvent-containing substance, as well as to provide a method for removing a solvent-containing substance 25 using the pressure-sensitive adhesive sheet. The

solvent-containing substance includes, for example, a paste turned about the back of a screen printing plate, an ink remained on a blanket cylinder of an offset printing machine, and an ink stain in the vicinity of an ink jet orifice of an  
5 ink jet printer.

Another object of the present invention is to provide a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which can reliably and quickly adhere to and remove the solvent-containing substance without  
10 staining of an article to be treated such as a screen printing plate with components derived from the pressure-sensitive adhesive sheet, as well as to provide a method for removing a solvent-containing substance using the pressure-sensitive adhesive sheet.

15 A further object of the present invention is to provide a sheet for removal of a solvent-containing substance, which can reliably adhere to and remove the solvent-containing substance deposited on, for example, a machine or floor without broadening stains toward surroundings, as well as to  
20 provide a method for removing a solvent-containing substance using the pressure-sensitive adhesive sheet.

Yet another object of the present invention is to provide a pressure-sensitive adhesive sheet for removal of solvent-containing substance, which can easily clean an  
25 article to be cleaned, does not damage the article and does

not broaden stains, as well as to provide a method for removing a solvent-containing substance using the pressure-sensitive adhesive sheet.

Still another object of the present invention is to  
5 provide a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which is highly versatile and can be applied to a wide variety of articles to be cleaned and solvent-containing substances (deposits), as well as to provide a method for removing a solvent-containing substance  
10 using the pressure-sensitive adhesive sheet.

Another object of the present invention is to provide a method for removing a solvent-containing substance, which method can easily select and use an optimum pressure-sensitive adhesive sheet depending on the type of a solvent in the  
15 solvent-containing substance deposited on an article to be cleaned.

A further object of the present invention is to provide a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which can satisfactorily  
20 remove the solvent-containing substance such as a paste turned about the back of a screen printing plate and can be peeled off without damaging the article to be cleaned such as the screen printing plate, as well as to provide a method for removing a solvent-containing substance using the  
25 pressure-sensitive adhesive sheet.

Yet another object of the present invention is to provide a sheet for removal of a solvent-containing substance, which can efficiently remove the solvent-containing substance such as a paste turned about the back of a screen printing plate 5 while preventing electrostatic buildup, as well as to provide a method for removing a solvent-containing substance using the sheet.

After intensive investigations to achieve the above objects, the present inventors have found that, when a pressure-sensitive adhesive sheet contains a pressure-sensitive adhesive layer that can absorb at least a predetermined amount of a solvent contained in a solvent-containing substance to be removed, the resulting pressure-sensitive adhesive sheet can reliably adhere to and remove the solvent-containing substance to be removed, that, when a pressure-sensitive adhesive sheet contains a pressure-sensitive adhesive layer that can absorb at least a predetermined amount of a solvent contained in a solvent-containing substance to be removed in a short time and 20 has a tackiness within a specific range after absorbing the solvent, the resulting pressure-sensitive adhesive sheet can reliably adhere to and remove the solvent-containing substance to be removed, and that, when a pressure-sensitive adhesive sheet has a pressure-sensitive adhesive layer that 25 can absorb at least a predetermined amount of a solvent

contained in a solvent-containing substance to be removed in  
a short time, and components constituting the  
pressure-sensitive adhesive layer do not migrate into an  
adherend in a predetermined peel test after absorbing a  
5 predetermined amount of the solvent, the resulting  
pressure-sensitive adhesive sheet can efficiently remove the  
solvent-containing substance to be removed from an article to  
be treated without staining of the article to be treated after  
the removal.

10        Additionally, the present inventors have found a relation  
between the capability of a pressure-sensitive adhesive sheet  
for removal of a solvent-containing substance and the  
dissolving property of a pressure-sensitive adhesive  
constituting a pressure-sensitive adhesive layer. The  
present inventors therefore have made further investigations  
15 on solubility parameters that are used as indicators of  
dissolution phenomenon and have found that the  
pressure-sensitive adhesive sheet can reliably adhere to and  
remove a solvent-containing substance without broadening the  
20 same toward surroundings, when the solubility parameter of the  
pressure-sensitive adhesive is in a specific relation with the  
solubility parameter of a solvent contained in the  
solvent-containing substance to be removed.

25        The present inventors have further found that, when a  
pressure-sensitive adhesive sheet has a pressure-sensitive

adhesive layer containing fine particles, the resulting pressure-sensitive adhesive sheet can reliably adhere to and remove a solvent-containing substance such as a paste (an ink) turned about the back of a screen printing plate without damaging  
5 the article to be cleaned such as the screen printing plate.

In addition, the present inventors have found that, when a sheet for removal of a solvent-containing substance has been subjected to antistatic treatment, the resulting sheet can prevent electrostatic buildup during a process of removing a solvent-containing substance such as a paste (an ink) turned about the back of a screen printing plate and can prevent the occurrence of malfunctions caused by the static electricity.  
10

The present invention has been accomplished based on these findings.

15 Specifically, the present invention provides a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which pressure-sensitive adhesive sheet includes a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate.

20 In this pressure-sensitive adhesive sheet (hereinafter briefly referred to as "sheet 1 for removal of a solvent-containing substance"), the pressure sensitive adhesive layer adsorbs 20 g/m<sup>2</sup> or more of a solvent contained in the substance to be removed when the pressure-sensitive  
25 adhesive sheet is immersed in the solvent for 3 minutes.

The present invention provides a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which pressure-sensitive adhesive sheet includes a substrate and a pressure sensitive adhesive layer formed at least on one side of the substrate. In this pressure-sensitive adhesive sheet (hereinafter briefly referred to as "sheet 2 for removal of a solvent-containing substance"), the pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of the solvent has a tackiness of 1 cN/25-mm or more as determined by a method in conformity with Japanese Industrial Standards (JIS) Z 0237.

The present invention further provides a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which includes a substrate and a pressure sensitive adhesive layer formed at least on one side of the substrate. In this pressure-sensitive adhesive sheet (hereinafter briefly referred to as "sheet 3 for removal of a solvent-containing substance"), the pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and no stain is observed in a stainless steel plate (a SUS 430BA

plate) by visual inspection when the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of the solvent is stuck to the stainless steel plate by a reciprocating motion of a 2-kg rubber roller and is peeled off from the stainless steel plate. In the sheet 3 for removal of a solvent-containing substance, a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer may include insoluble components alone with respect to the solvent contained in the substance to be removed.

10       The present invention further provides a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which includes a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate. In this pressure-sensitive adhesive sheet (hereinafter briefly referred to as "sheet 4 for removal of a solvent-containing substance"), a difference  $\Delta\delta$  between the solubility parameter (SP)  $\delta_1$  [ $(J/cm^3)^{1/2}$ ] of a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer and the solubility 15 parameter (SP)  $\delta_2$  [ $(J/cm^3)^{1/2}$ ] of a solvent contained in the solvent-containing substance to be removed falls within a range of  $\pm 4$  [ $(J/cm^3)^{1/2}$ ].

20       The present invention still further provides a pressure-sensitive adhesive sheet for removal of a solvent-containing substance, which includes a substrate and 25

a pressure-sensitive adhesive layer formed at least on one side of the substrate. In this pressure-sensitive adhesive sheet (hereinafter briefly referred to as "sheet 5 for removal of a solvent-containing substance"), the pressure-sensitive adhesive layer contains fine particles. The fine particles may have a mean particle size of, for example, from about 0.01 to about 10  $\mu\text{m}$ .

In the sheets 1 to 5 for removal of a solvent-containing substance, the pressure-sensitive adhesive layer before use may have a tackiness of from 1 to 400 cN/25-mm as determined by a method in conformity with JIS Z 0237. The sheets 1 to 5 for removal of a solvent-containing substance are for use in cleaning of a screen printing plate, for example.

The present invention provides, in another aspect, a method for removing a solvent-containing substance deposited on an article to be cleaned, which method includes the step of using a pressure-sensitive adhesive sheet, and the pressure-sensitive adhesive sheet includes a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate. In this method (hereinafter briefly referred to as "removing method 1"), the pressure sensitive adhesive layer adsorbs 20 g/m<sup>2</sup> or more of a solvent contained in the solvent-containing substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 3 minutes.

The present invention additionally provides a method for removing a solvent-containing substance deposited on an article to be cleaned, which method includes the step of using a pressure-sensitive adhesive sheet, and the

5 pressure-sensitive adhesive sheet includes a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate. In this method (hereinafter briefly referred to as "removing method 2"), the pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the solvent-containing substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of the solvent has a tackiness of 1 cN/25-mm or more as determined by a method in conformity with JIS Z 0237.

10 15 The present invention still further provides a method for removing a solvent-containing substance deposited on an article to be cleaned, which method includes the step of using a pressure-sensitive adhesive sheet including a substrate and a pressure-sensitive adhesive layer formed at least on one 20 side of the substrate. In this method (hereinafter briefly referred to as "removing method 3"), the pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and 25 no stain is observed in a stainless steel plate (a SUS 430BA

plate) by visual inspection when the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of the solvent is stuck to a stainless steel plate by a reciprocating motion of a 2-kg rubber roller and is peeled off from the stainless steel plate.

5       The present invention further provides a method for removing a solvent-containing substance deposited on an article to be cleaned by using a pressure-sensitive adhesive sheet including a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate. This  
10      method (hereinafter briefly referred to as "removing method 4") includes the steps of (a) determining the solubility parameter (SP)  $\delta_1$  [(J/cm<sup>3</sup>)<sup>1/2</sup>] of a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer, (b) determining the solubility parameter (SP)  $\delta_2$  [(J/cm<sup>3</sup>)<sup>1/2</sup>] of a solvent contained in the solvent-containing substance to be removed, and (c) selecting such a pressure-sensitive adhesive sheet that a difference  $\Delta\delta$  between  $\delta_1$  and  $\delta_2$  falls within a range of  $\pm 4$  [(J/cm<sup>3</sup>)<sup>1/2</sup>] and removing the solvent-containing substance with the use of the selected pressure-sensitive  
15      adhesive sheet. In Step (a), the pressure-sensitive adhesive sheet may be immersed respectively in plural solvents having different solubility parameters (SPs) to determine the degree of swelling or gel fraction of the pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer, and the  
20      solubility parameter (SP) of a solvent, in which the  
25

pressure-sensitive adhesive exhibits the maximum degree of swelling or the minimum gel fraction, may be defined as the solubility parameter (SP)  $\delta_1$  [ $(J/cm^3)^{1/2}$ ] of the pressure-sensitive adhesive constituting the  
5 pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet.

The present invention provides a method for removing a solvent-containing substance deposited on an article to be cleaned, which method includes the step of using a

10 pressure-sensitive adhesive sheet including a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate. In this method (hereinafter briefly referred to as "removing method 5"), the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet  
15 contains fine particles.

In addition, the present invention provides a sheet for removal of a solvent-containing substance, which sheet includes a substrate and a pressure-sensitive adhesive layer or a foam layer formed at least on one side of the substrate.  
20 This sheet (hereinafter briefly referred to as "sheet 6 for removal of a solvent-containing substance") has been subjected to antistatic treatment. In the sheet 6 for removal of a solvent-containing substance, at least one of both sides of the sheet may have a surface resistivity of  $10^{13} \Omega$  or less.  
25 The sheet 6 for removal of a solvent-containing substance may

be for use in cleaning of a screen printing plate.

In addition and advantageously, the present invention provides a method for removing a solvent-containing substance deposited on an article to be cleaned, which method includes 5 the step of using a sheet including a substrate and a pressure-sensitive adhesive layer or a foam layer formed at least on one side of the substrate. In this method (hereinafter briefly referred to as "removing method 6"), the sheet has been subjected to antistatic treatment.

10 Best Mode for Carrying Out the Invention

Substrates (bases) for use in the invented sheets for removal of a solvent-containing substance are not specifically limited. To avoid contamination of dust or foreign matters, polyethylene films, polypropylene films, and other polyolefin films; poly(ethylene terephthalate) films and other polyester films, and other plastic films can be advantageously used, since these plastic films do not form powdery paper dust. However, paper and similar substances 15 can be used as the substrate when the sheets are used for simple cleaning of, for example, rollers. Foam of polyurethanes, polyethylenes, ethylene-propylene-diene rubber (EPDM) and other materials can be advantageously used as the substrate for removal of pastes or inks on uneven surfaces.

20 Additionally, unwoven fabrics, cloths and metallic foils can

also be used as the substrate in some applications.

The thickness of the substrate is not specifically limited and can be appropriately set in view of required strength and workability and is generally from about 10 to about 500  $\mu\text{m}$ , preferably from about 12 to about 200  $\mu\text{m}$ , and more preferably from about 15 to about 100  $\mu\text{m}$ . When the substrate is a foam, it generally has a thickness of from about several millimeters to about several ten millimeters.

Pressure-sensitive adhesives (tacky adhesives) for constituting the pressure-sensitive adhesive layer of the invented sheets for removal of a solvent-containing substance are not specifically limited, and any pressure-sensitive adhesives can be used as far as the aforementioned characteristics according to the present invention can be obtained. Such pressure-sensitive adhesives include, but are not limited to, rubber pressure-sensitive adhesives (e.g., natural rubber pressure-sensitive adhesives; styrene-butadiene copolymer, polyisobutylene, styrene-isoprene-styrene copolymer, and other pressure-sensitive adhesives) and acrylic pressure-sensitive adhesives. Among them, acrylic pressure-sensitive adhesives are preferred.

Such acrylic pressure-sensitive adhesives generally comprise a base monomer for imparting adhesion, a comonomer for imparting cohesiveness (agglomeration

property) and a functional-group-containing monomer for improving tackiness or for forming crosslinking points. Such base monomers include, but are not limited to, ethyl acrylate, propyl acrylate, isopropyl acrylate, butyl acrylate, isobutyl 5 acrylate, pentyl acrylate, hexyl acrylate, heptyl acrylate, octyl acrylate, 2-ethylhexyl acrylate, nonyl acrylate, decyl acrylate, and other acrylic C<sub>2</sub>-C<sub>10</sub> alkyl esters.

The comonomer for imparting cohesiveness includes, but is not limited to, methyl acrylate; methyl methacrylate, ethyl 10 methacrylate, isopropyl methacrylate, and other alkyl methacrylates; vinyl acetate and other vinyl esters; styrene,  $\alpha$ -methylstyrene, vinyltoluene, and other styrenic monomers; and acrylonitrile, of which vinyl esters and acrylonitrile are preferred.

15 The functional-group-containing monomer includes, but is not limited to, acrylic acid, methacrylic acid, itaconic acid, maleic anhydride, and other monomers each containing a carboxyl group or an acid anhydride group; 2-hydroxyethyl acrylate, 2-hydroxyethyl methacrylate, hydroxypropyl 20 methacrylate, and other hydroxyl-group-containing monomers; glycidyl acrylate, glycidyl methacrylate, and other epoxy-group-containing monomers; N-methylolacrylamide, N-methylolmethacrylamide, and other amido-group-containing monomers; dimethylaminoethyl methacrylate, t-butylaminoethyl methacrylate, and other 25

amino-group-containing monomers. Among them, acrylic acid and other monomers each containing a carboxyl group or an acid anhydride group are preferred as the functional-group-containing monomer.

5       The proportions of the base monomer, the comonomer and the functional-group-containing monomer each constituting the acrylic pressure-sensitive adhesive can be appropriately selected depending on, for example, the type of the solvent-containing substance to be removed (the type of a  
10 solid matter and the type of a solvent). For example, the base monomer occupies from about 40% to about 98% by weight and preferably from about 50% to about 95% by weight, the comonomer occupies from about 0% to about 50% by weight and preferably from about 2% to about 40% by weight, and the  
15 functional-group-containing monomer occupies from about 0.5% to about 15% by weight and preferably from about 1% to about 10% by weight of the total monomer components.

The pressure-sensitive adhesive layer may further comprise various additives in addition to the  
20 pressure-sensitive adhesive polymer (base polymer). Such additives include, but are not limited to, crosslinking agents (e.g., isocyanate crosslinking agents, epoxy crosslinking agents, urea crosslinking agents, melamine crosslinking agents, carboxylic-acid or acid-anhydride crosslinking agents, metallic-compound crosslinking agents), tackifiers  
25

[e.g., terpene resins, terpene-phenol resins, modified aromatic terpene resins, hydrogenated terpene resins, and other terpene resins; aliphatic, aromatic, or alicyclic petroleum resins; rosin, hydrogenated rosin esters, and other  
5 rosin resins; coumarone-indene resins; and styrenic resins], surfactants [e.g., phosphates, sulfates, sulfonic acids, carboxylic acids, and other anionic surfactants; amine salts, quaternary ammonium salts, and other cationic surfactants; esters, ethers, ester-ethers, alkanolamides, and other  
10 nonionic surfactants; carboxy betaines, glycine, and other amphoteric surfactants], plasticizers, antioxidants, coloring agents, antistatic agents, fillers, and foaming agents. Preferred crosslinking agents include isocyanate crosslinking agents, and preferred tackifiers include  
15 terpene-phenol resins and other terpene resins.

The amounts of these additives can be appropriately selected within ranges not deteriorating tackiness and solvent absorptivity. For example, the amount of crosslinking agent is from about 1 to about 30 parts by weight  
20 and preferably from about 2 to about 15 parts by weight relative to 100 parts by weight of the pressure-sensitive adhesive polymer (base polymer). The amount of the surfactant is from about 0 to about 10 parts by weight (e.g., from about 0.1 to about 10 parts by weight) and preferably from  
25 about 0 to about 5 (e.g., from about 0.2 to about 5 parts by

weight) relative to 100 parts by weight of the pressure-sensitive adhesive polymer (base polymer).

In the invented sheet 3 for removal of a solvent-containing substance, the pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer should be preferably composed of components alone which are insoluble in a solvent contained in the substance to be removed. For example, additives such as plasticizers and surfactants other than crosslinking agents tend to dissolve into a solvent contained in, for example, a paste for screen printing, and the sheet 3 for removal of a solvent-containing substance should preferably contain the minimum amounts of these additives. Additionally, it is better to avoid addition of such additives as to be dissolved in the solvent contained in the substance to be removed (to be dissolved out into the solvent).

In the present invention, the pressure-sensitive adhesive layers of the pressure-sensitive adhesive sheets before use preferably have a tackiness (adhesive strength) of 400 cN/25-mm or less (e.g., from 1 to 400 cN/25-mm) as determined by a method in conformity with JIS Z 0237. The tackiness is determined after 1-minute contact-bonding of the pressure-sensitive adhesive sheet and a test plate, a SUS 430BA plate. The upper and lower limits of the tackiness are more preferably 300 cN/25-mm and 3 cN/25-mm, respectively.

If the tackiness before use exceeds 400 cN/25-mm, the resulting pressure-sensitive adhesive sheet becomes resistant to peeling off from, for example, a screen printing plate, and an emulsion may be peeled off from the screen printing plate, or repeated operations may elongate the screen to thereby invite imperfect printing. If the tackiness before use is less than 1 cN/25-mm, the pressure-sensitive adhesive surface becomes resistant to adhere to, for example, a paste turned about the back of the printing plate, and a desired cleaning effect cannot be significantly obtained.

The tackiness of the pressure-sensitive adhesive sheets before use can be controlled by appropriately selecting the types and proportions of constitutional monomers, the type and proportion of the crosslinking agent, glass transition temperature, and average molecular weight of the pressure-sensitive adhesive (resin) constituting the pressure-sensitive adhesive layer, the thickness of the pressure-sensitive adhesive layer, and the type, particle size and amount of the fine particles in the pressure-sensitive adhesive layer.

The thickness of the pressure-sensitive adhesive layer can be freely selected depending on the intended use within a range in which the characteristics according to the present invention can be obtained, and is, for example, from about 5 to about 5000  $\mu\text{m}$ , and preferably from about 10 to about 2000

μm. The pressure-sensitive adhesive sheets may further comprise an undercoat between the substrate and the pressure-sensitive adhesive layer and may have pressure-sensitive adhesive layers on both sides of the 5 substrate. The pressure-sensitive adhesive layer can be formed on the substrate by conventional techniques such as coating.

Solvent-containing substances (materials) to be removed according to the present invention are not specifically limited and include semisolid substances (materials) that contain solvents and are in wet conditions, such as pastes, 10 inks, glues, adhesives, and paints (coating materials).

Solvents contained in the solvent-containing substances include, but are not limited to, hexane, heptane, mineral 15 spirit, and other aliphatic hydrocarbons; cyclohexane and other alicyclic hydrocarbons; toluene, xylene, solvent naphtha, tetralin, dipentene, and other aromatic hydrocarbons; methyl alcohol, ethyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, s-butyl alcohol, 20 cyclohexyl alcohol, 2-methylcyclohexyl alcohol, tridecyl alcohol, and other alcohols; methyl acetate, ethyl acetate, isopropyl acetate, butyl acetate, and other esters; acetone, methyl ethyl ketone, methyl isobutyl ketone, cyclohexanone, methylcyclohexanone, diacetone alcohol, isophorone, and 25 other ketones; ethylene glycol, propylene glycol, diethylene

glycol, triethylene glycol, dipropylene glycol, and other  
glycols; butyl  $\beta$ -hydroxyethyl ether (butyl cellosolve),  
propylene glycol monomethyl ether, propylene glycol monoethyl  
ether, propylene glycol monobutyl ether, diethylene glycol  
5 monobutyl ether, and other glycol ethers; butyl cellosolve  
acetate, propylene glycol monomethyl ether acetate, propylene  
glycol monoethyl ether acetate, diethylene glycol monobutyl  
ether acetate, and other glycol ether esters; and water. In  
the case of inks for screen printing, medium-boiling solvents  
10 (boiling point: from about 120°C to about 230°C) and  
high-boiling solvents (boiling point: from about 230°C to  
about 320°C) are frequently used. Typical solvents for use  
in determination of the solvent absorption are diethylene  
glycol monobutyl ether acetate and diethylene glycol  
15 monobutyl ether [e.g., a mixture of diethylene glycol  
monobutyl ether acetate and diethylene glycol monobutyl ether  
[9:1 (by weight)]].

An important feature of the invented sheet 1 for removal  
of a solvent-containing substance is that (i) the  
20 pressure-sensitive adhesive layer absorbs 20 g/m<sup>2</sup> or more of  
a solvent contained in the substance to be removed when the  
pressure-sensitive adhesive sheet is immersed in the solvent  
for 3 minutes.

An important feature of the invented sheet 2 for removal  
25 of a solvent-containing substance is that (ii) the

pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and (iii) the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of the solvent has a tackiness (adhesive strength) of 1 cN/25-mm or more as determined by a method in conformity with JIS Z 0237.

An important feature of the invented sheet 3 for removal of a solvent-containing substance is that (ii) the

10 pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and (iv) no stain is observed in a stainless steel plate (a SUS 430BA plate) by visual inspection when the  
15 pressure-sensitive adhesive sheet (20 mm wide) after absorbing 5 g/m<sup>2</sup> of the solvent is stuck to the stainless steel plate by a reciprocating motion of a 2-kg rubber roller and is peeled off from the stainless steel plate.

The absorption of the solvent (hereinafter referred to  
20 as "solvent absorption") in the characteristics (i) and (ii)  
is determined in the following manner: A sample of a  
pressure-sensitive adhesive sheet is cut to 30 to 50 mm square  
and is weighed, and the weighed sample is immersed in a solvent  
contained in a solvent-containing substance to be removed for  
25 3 minutes or for 1 second, is taken out from the solvent, the

solvent deposited on a surface of the sheet is immediately wiped off with a waste rag, and the sample is again weighed to thereby calculate increase in weight per unit area. The tackiness in the characteristic (iii) is determined one minute  
5 after the tested pressure-sensitive adhesive sheet is pressed to a test plate, SUS 430BA. The visual inspection in the characteristic (iv) can be performed according to the visual inspection to verify migration of a pressure-sensitive adhesive of a pressure-sensitive adhesive tape as specified  
10 in Japanese Industrial Standards.

In assumed applications of the present invention, the time of contact between the pressure-sensitive adhesive sheet and a cleaning region carrying a solvent-containing substance to be removed is not so long and is assumed to be within 10 minutes.  
15 When the solvent absorption of the pressure-sensitive adhesive sheet is determined by the aforementioned method to thereby find the relation between the time of immersing the pressure-sensitive adhesive sheet in a solvent (up to 10 minutes) and the solvent absorption, the solvent absorption becomes almost saturated in 3 minutes.  
20 Consequently, by specifying the solvent absorption when the pressure-sensitive adhesive sheet is immersed in a solvent for 3 minutes (nearly equal to saturated solvent absorption) at a predetermined level or higher as in the characteristic (i),  
25 a pressure-sensitive adhesive sheet suitable for the

application can be specified. In the characteristic (ii), the solvent absorption when the pressure-sensitive adhesive sheet is immersed in a solvent for 1 second is specified. This is because the time of contact between the pressure-sensitive adhesive sheet and a cleaning region carrying a solvent-containing substance to be removed is preferably minimized when the article to be cleaned tends to cause troubles when it is contaminated with components derived from the pressure-sensitive adhesive sheet, and the

5 solvent-containing substance must be removed as efficiently as possible. In addition, in the case where the time of contact between the pressure-sensitive adhesive sheet and the cleaning region is short, for example, in the case when the pressure-sensitive adhesive sheet is stuck to and is

10 immediately peeled off from the cleaning region, the pressure-sensitive adhesive layer must absorb at least a predetermined amount of the solvent in 1 second.

15

In the sheet 1 for removal of a solvent-containing substance, the solvent absorption in the characteristic (i) should be 20 g/m<sup>2</sup> or more for sufficient advantages, is more 20 preferably 25 g/m<sup>2</sup> or more and is further preferably 30 g/m<sup>2</sup> or more. The upper limit of the solvent absorption is not especially specified and is generally about 100 g/m<sup>2</sup>. The solvent absorption in the sheet 1 for removal of a

25 solvent-containing substance can be controlled by

appropriately selecting the types and proportions of constitutional monomers, the type and proportion of the crosslinking agent, glass transition temperature, and average molecular weight of the pressure-sensitive adhesive (base polymer) constituting the pressure-sensitive adhesive layer, and the thickness of the pressure-sensitive adhesive layer.

The solvent absorption in the characteristic (ii) is should be 5 g/m<sup>2</sup> or more for sufficient advantages, is more preferably 6 g/m<sup>2</sup> or more and is further preferably 7 g/m<sup>2</sup> or more. The upper limit of the solvent absorption is not especially specified and is generally about 50 g/m<sup>2</sup>. The tackiness after absorbing 5 g/m<sup>2</sup> of a solvent in the characteristic (iii) as determined by the above method should be preferably 1 cN/25-mm or more (e.g., from about 1 to about 200 cN/25-mm) for good results, is more preferably 3 cN/25-mm or more (e.g., from about 3 to about 100 cN/25-mm). The solvent absorption and tackiness after absorbing 5 g/m<sup>2</sup> of the solvent can be controlled by appropriately selecting the types and proportions of constitutional monomers, the type and proportion of the crosslinking agent, glass transition temperature and average molecular weight of the pressure-sensitive adhesive (base polymer) constituting the pressure-sensitive adhesive layer, the thickness of the pressure-sensitive adhesive layer, and the types and amounts of additives added to the pressure-sensitive adhesive layer.

In the sheet 3 for removal of a solvent-containing substance, the solvent absorption in the characteristic (ii) should be 5 g/m<sup>2</sup> or more for sufficient advantages, is more preferably 6 g/m<sup>2</sup> or more and is further preferably 7 g/m<sup>2</sup> or 5 more. The upper limit of the solvent absorption is not especially specified and is generally about 50 g/m<sup>2</sup>. The tackiness after absorbing 5 g/m<sup>2</sup> of the solvent is preferably 1 cN/25-mm or more (e.g., from about 1 to about 200 cN/25-mm) and more preferably 3 cN/25-mm or more (e.g., from about 1 to 10 about 100 cN/25-mm) as determined by the method in conformity with JIS Z 0237, in which a SUS 430BA plate is used as a test plate, and the tackiness is measured after 1-minute contact-bonding of the pressure-sensitive adhesive sheet and the test plate. The characteristics (ii) and (iv) of the sheet 3 for removal of a solvent-containing substance can be controlled by appropriately selecting the types and proportions of constitutional monomers, the type and proportion of the crosslinking agent, glass transition temperature, and average molecular weight of the 15 pressure-sensitive adhesive (base polymer) constituting the pressure-sensitive adhesive layer, the thickness of the pressure-sensitive adhesive layer, and the types and amounts of additives added to the pressure-sensitive adhesive layer.

According to the invented sheet 1 for removal of a 25 solvent-containing substance and removing method 1, the

pressure-sensitive adhesive sheet can absorb 20 g/m<sup>2</sup> or more of a solvent contained in a solvent-containing substance such as a paste (an ink) for use in screen printing or an ink deposited on a roll of a printing machine such as an offset

5 printing machine. Accordingly, by sticking the pressure-sensitive adhesive sheet to the back of a screen printing plate or the roll, the pressure-sensitive adhesive sheet can absorb almost all of the solvent contained in the paste turn about the back of the screen printing plate or the  
10 ink deposited on the roll to thereby solidify the paste or ink. Additionally, the pressure-sensitive adhesive sheet has sufficient and extra solvent absorptivity, and the pressure-sensitive adhesive sheet still has some tackiness remained in the sheet even after absorbing a predetermined  
15 amount of the solvent. Accordingly, when the pressure-sensitive adhesive sheet is peeled off from the article to be treated, the solidified matter after absorption of the solvent is stuck to the pressure-sensitive adhesive sheet and is removed off from the article to be cleaned. Thus,  
20 the pressure-sensitive adhesive sheet can highly effectively remove the solvent-containing substance. If the pressure-sensitive adhesive sheet does not have sufficient solvent absorptivity, it loses tackiness at the time when it absorbs the solvent to thereby fail to remove the  
25 solvent-containing substance.

According to the invented sheet 2 for removal of a solvent-containing substance and removing method 2, the pressure-sensitive adhesive sheet can absorb, in a short time, 5 g/m<sup>2</sup> or more of a solvent contained in a solvent-containing substance such as a paste (an ink) for use in screen printing or an ink deposited on a roll of a printing machine such as an offset printing machine. Accordingly, by sticking the pressure-sensitive adhesive sheet to the back of a screen printing plate or the roll, the pressure-sensitive adhesive sheet can efficiently absorb, in a short time, the solvent contained in the paste turned about the back of the screen printing plate or the ink deposited on the roll to thereby solidify the paste or ink. Additionally, the pressure-sensitive adhesive sheet still has remained tackiness of 1 CN/25-mm or more even after absorbing a predetermined amount of the solvent. Accordingly, when the pressure-sensitive adhesive sheet is peeled off from the article to be treated, the solidified matter after absorption of the solvent is stuck to the pressure-sensitive adhesive sheet and is removed off from the article to be treated. Thus, the pressure-sensitive adhesive sheet can highly effectively remove the solvent-containing substance.

According to the invented sheet 3 for removal of a solvent-containing substance and removing method 3, the pressure-sensitive adhesive sheet can absorb, in a short time,

5 g/m<sup>2</sup> or more of a solvent contained in a solvent-containing substance such as a paste (an ink) for use in screen printing or an ink deposited on a roll of a printing machine such as an offset printing machine. Accordingly, by sticking the  
5 pressure-sensitive adhesive sheet to the back of a screen printing plate or the roll, the pressure-sensitive adhesive sheet can immediately absorb almost all of the solvent contained in the paste turned about the back of the screen printing plate or the ink deposited on the roll to solidify  
10 the paste or ink to thereby efficiently remove the paste or ink. The pressure-sensitive adhesive sheet used herein has a characteristic in that components of the pressure-sensitive adhesive layer do not migrate into an adherend in the predetermined peel test after absorbing the predetermined  
15 amount of a solvent, and the components of the pressure-sensitive adhesive layer do not contaminate or stain a surface of an article to be treated after removing the solvent-containing substance deposited on the article to be treated.

20 An important feature of the invented sheet 4 for removal of a solvent-containing substance is that a difference  $\Delta\delta$  between the solubility parameter (SP)  $\delta_1$  [ $(J/cm^3)^{1/2}$ ] of a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer and the solubility  
25 parameter (SP)  $\delta_2$  [ $(J/cm^3)^{1/2}$ ] of a solvent contained in the

solvent-containing substance to be removed falls within a range of  $\pm 4$  [ $(J/cm^3)^{1/2}$ ].

When the solubility parameter  $\delta_1$  of the pressure-sensitive adhesive satisfies the above relation, the

5 pressure-sensitive adhesive rapidly absorbs the solvent in the solvent-containing substance to be removed, and the pressure-sensitive adhesive constituting the

pressure-sensitive adhesive layer maintains its tackiness (adhesion). Accordingly, the pressure-sensitive adhesive

10 sheet can reliably adhere to and remove the solvent-containing substance from the article to be cleaned without broadening stains toward surroundings. In contrast, if a

pressure-sensitive adhesive sheet, in which the solubility parameter  $\delta_1$  [ $(J/cm^3)^{1/2}$ ] of the pressure-sensitive adhesive

15 does not satisfy the above relation, is stuck to a solvent-containing substance, a solvent in the solvent-containing substance cannot be significantly absorbed by the pressure-sensitive adhesive and the tackiness (adhesion) of the pressure-sensitive adhesive is destroyed.

20 Accordingly, stained portions are broadened and the solvent-containing substance cannot be removed by action of tackiness. The difference  $\Delta\delta$  more preferably falls within a range of  $\pm 3$  [ $(J/cm^3)^{1/2}$ ].

The solubility parameter (SP)  $\delta_1$  [ $(J/cm^3)^{1/2}$ ] of the

25 pressure-sensitive adhesive constituting the

pressure-sensitive adhesive layer can be determined, for example, by the following method. Specifically, the pressure-sensitive adhesive sheet is immersed in several types (at least three types) of solvents having different 5 solubility parameters (SPs); the degree of swelling or gel fraction of the pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer is determined; and the solubility parameter (SP) of a solvent, in which the pressure-sensitive adhesive exhibits the maximum degree of 10 swelling or the minimum gel fraction, is defined as the solubility parameter (SP) (typical) of the pressure-sensitive adhesive. The solubility parameters (SPs) of solvents can be obtained by calculation according to the Fedors method or from known data books or lists.

15       Typical solvents for use in the determination of the solubility parameter (SP) of the pressure-sensitive adhesive include, for example, n-heptane (15.1), cyclohexane (16.8), toluene (18.1), ethyl acetate (18.6), methyl ethyl ketone (19.0), cyclohexanone (20.3), isobutyl alcohol (21.5), and 20 isopropyl alcohol (23.5). The figures in the parentheses are solubility parameters (SPs) [ $(J/cm^3)^{1/2}$ ].

The degree of swelling and gel fraction of the pressure-sensitive adhesive can be determined in the following manner:

25       (1) Accurately weigh a Teflon film (about 10 cm square)

and a kite string (about 12 cm long) for use in the determination (A g).

(2) Wrap about 0.5 to about 1 g of the pressure-sensitive adhesive (or pressure-sensitive adhesive sheet) with the Teflon film using the kite string. Additionally, wrap a substrate alone used in the pressure-sensitive adhesive sheet in the same manner to thereby yield a blank sample.

(3) Accurately weigh the package of the sample prepared in step (2), and subtract the weight of the Teflon film and kite string determined in step (1) (A g) from the weight of the package to thereby determine the sample weight (B g).

(4) Place the above package in a glass bottle of from 50 to 300 ml capacity, and place a solvent to be determined in the glass bottle, and immerse the package therein at room temperature for 7 days.

(5) Take out the package from the glass bottle, quickly wipe off the solvent deposited on the Teflon film, and accurately weigh the resulting package (C g).

(6) Dry the weighed package in an oven (dryer) at 130°C for 2 hours.

(7) Accurately weigh the dried package (D g).

(8) Calculate the degree of swelling according to the following equation.

$$\text{Degree of swelling (\%)} = \{(C-A)/(D-A)\} \times 100$$

When the pressure-sensitive adhesive sheet is used as the

sample, the values obtained by subtracting the values of the blank sample (substrate alone) from measured values are used as C and D in calculation.

(9) Calculate the gel fraction according to the following

5 equation.

$$\text{Gel fraction (\%)} = \{(D-A)/B\} \times 100$$

When the pressure-sensitive adhesive sheet is used as the sample, the values obtained by subtracting the values of the blank sample (substrate alone) from measured values are used  
10 as B and D in calculation.

In the above determination, when a highly viscous solvent is used, a nylon gauze can be used instead of the Teflon film. When a high boiling solvent is used, the drying temperature should be set in the vicinity of the boiling point of the  
15 solvent.

When the pressure-sensitive adhesive is polyisobutylene or another pressure-sensitive adhesive that is not crosslinked and completely dissolves out in a solvent, the solubility parameter (SP) of the pressure-sensitive adhesive  
20 can be determined in the same manner as above, except that the time period for immersing the sample in the solvent is shortened. Alternatively, the solve-out rate of the pressure-sensitive adhesive is calculated from the test results, and the solubility parameter (SP) of a solvent, in  
25 which the pressure-sensitive adhesive exhibits the maximum

solve-out rate, may be determined as the solubility parameter (SP) (typical) of the pressure-sensitive adhesive.

When the solubility parameter (SP) of the polymer of the pressure-sensitive adhesive in question is listed as a value obtained as a result of precedent tests or calculation in literature such as "Polymer Handbook" (John Wiley & Sons, Inc.), the listed value may be employed as the solubility parameter (SP)  $\delta_1$  of the pressure-sensitive adhesive for use in the present invention.

The solubility parameter (SP)  $\delta_2$  [ $(J/cm^3)^{1/2}$ ] of the solvent contained in the solvent-containing substance to be removed can also be determined by calculation according to the Fedors method or from known data books. When plural solvents are contained in the solvent-containing substance to be removed, the total sum of the products of the solubility parameters (SPs) and molar fractions of the individual solvents can be used as the solubility parameter (SP)  $\delta_2$ . However, if at least one of the plural solvents is a solvent that does not solve the pressure-sensitive adhesive, the degree of swelling or gel fraction is determined according to the above method using plural polymers having known SPs listed in literature such as "Polymer Handbook", and SP of a polymer which exhibits the maximum degree of swelling or the minimum gel fraction can be defined as the solubility parameter (SP)  $\delta_2$  of the solvent mixture composed of the plural solvents. The

solubility parameter (SP)  $\delta_2$  of the solvent mixture can also be determined by calculation from the value of latent heat of evaporation, vapor pressure, or other physical properties by known techniques.

5        In the invented sheet 4 for removal of a solvent-containing substance, the solubility parameter of a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet is in a specific relation with the solubility 10 parameter of a solvent contained in the solvent-containing substance to be removed, and the invented pressure-sensitive adhesive sheet can therefore rapidly absorb the solvent and can maintain its tackiness. Accordingly, the pressure-sensitive adhesive sheet can reliably adhere to and 15 remove solvent-containing substances deposited on, for example, machines or floors, without broadening stains toward surroundings. Additionally, the invented sheet 4 can easily clean an article to be cleaned without damaging the article and without broadening stains and can be applied to a wide 20 variety of articles to be cleaned and solvent-containing substances (deposits) to be removed. Accordingly, the invented sheet 4 for removal of a solvent-containing substance can realize cleaning operations using an adhesive sheet in printing and painting processes, which cleaning operations 25 have been performed only by wiping with wastes (wiping rags).

The invented removing method 4 includes, as described above, the steps of (a) determining the solubility parameter (SP)  $\delta_1$  [ $(J/cm^3)^{1/2}$ ] of a pressure-sensitive adhesive constituting a pressure-sensitive adhesive layer, (b) 5 determining the solubility parameter (SP)  $\delta_2$  [ $(J/cm^3)^{1/2}$ ] of a solvent contained in a solvent-containing substance to be removed, and (c) selecting such a pressure-sensitive adhesive sheet that a difference  $\Delta\delta$  between  $\delta_1$  and  $\delta_2$  falls within a range of  $\pm 4$  [ $(J/cm^3)^{1/2}$ ] and removing the solvent-containing 10 substance with the use of the selected pressure-sensitive adhesive sheet. According to this method, once SP of a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer in each pressure-sensitive adhesive sheet is determined, a usable pressure-sensitive adhesive sheet can be rapidly selected depending on the type 15 (structure) of the solvent contained in the solvent-containing substance to be removed which is deposited on an article to be cleaned.

An important feature of the invented sheet 5 for removal 20 of a solvent-containing substance is that the pressure-sensitive adhesive layer contains fine particles. The pressure-sensitive adhesive layer containing fine particles can be prepared by adding and dispersing the fine particles into a pressure-sensitive adhesive, and applying 25 the resulting pressure-sensitive adhesive composition to a

substrate. Such fine particles are not specifically limited as far as they are not miscible with the pressure-sensitive adhesive and include, for example, organic fine particles comprising poly(methyl methacrylate) resins, melamine resins, 5 and other synthetic resins or natural resins; inorganic fine particles comprising amorphous silica, alumina and other inorganic oxides, inorganic hydroxides and inorganic salts.

The content of the fine particles in the pressure-sensitive adhesive layer depends on the type of the 10 fine particles and is generally from about 5 to about 70 parts by weight, and preferably from about 10 to about 50 parts by weight relative to 100 parts by weight of the base polymer constituting the pressure-sensitive adhesive layer (a base polymer of the pressure-sensitive adhesive).

15 The pressure-sensitive adhesive layer containing the fine particles does not necessarily require to be prepared by adding and dispersing fine particles to a pressure-sensitive adhesive and applying the resulting pressure-sensitive adhesive composition. It is enough that the resulting 20 pressure-sensitive adhesive layer contains dispersed fine particles even though the pressure-sensitive adhesive composition is at first uniform. For example, when the pressure-sensitive adhesive layer is formed by applying a solvent-containing pressure-sensitive adhesive to a 25 substrate, the pressure-sensitive adhesive layer containing

fine particles can also be obtained in the following manner:  
A uniform pressure-sensitive adhesive composition containing  
components incorporated with each other, the solvent is  
removed by drying, and domains in the form of fine particles  
5 mainly containing a non-adhesive component are formed by phase  
separation. These domains in the form of fine particles such  
as in the island-in-sea structure are also included in the  
scope of the "fine particles" for use in the present invention.

More specifically, the pressure-sensitive adhesive layer  
10 containing fine particles can be prepared by adding a  
component to a pressure-sensitive adhesive composition before  
application, which component is soluble in the solvent for the  
application of the pressure-sensitive adhesive and becomes  
insoluble with the base polymer constituting the  
15 pressure-sensitive adhesive after application and drying. A  
typical example of such processes includes a process in which  
a crosslinking agent such as an isocyanate crosslinking agent  
is added to an acrylic pressure-sensitive adhesive in excess  
(e.g., from about 10 to about 30 parts by weight relative to  
20 100 parts by weight of the acrylic polymer), and the resulting  
composition is applied to a substrate to thereby form the  
pressure-sensitive adhesive layer. Alternatively, a vinyl  
chloride resin, vinyl acetate resin, a copolymer thereof, or  
a vinyl chloride-methyl methacrylate copolymer is added to an  
25 acrylic or rubber pressure-sensitive adhesive, and the

resulting composition is applied to a substrate to thereby form the pressure-sensitive adhesive layer.

The fine particles have a mean particle size of, for example, from about 0.01 to about 10  $\mu\text{m}$ , and preferably from about 0.01 to about 5  $\mu\text{m}$ . If the fine particles have a mean particle size of less than 0.01  $\mu\text{m}$ , the resulting pressure-sensitive adhesive sheet has excessively high tackiness and becomes resistant to be peeled off from an article to be cleaned such as a screen printing plate. If the fine particles have a mean particle size exceeding 10  $\mu\text{m}$ , the resulting pressure-sensitive adhesive sheet may have excessively low tackiness and to thereby less effectively remove a solvent-containing substance such as a paste turned about the back of the screen printing plate.

In the sheet 5 for removal of a solvent-containing substance, the pressure-sensitive adhesive layer preferably has a tackiness (adhesive strength) of from about 50 to about 400 cN/25-mm, and more preferably from about 100 to about 350 cN/25-mm as determined by the method in conformity with JIS Z 0237, in which a SUS 430BA plate is used as a test plate, and the tackiness is measured after 1-minute contact-bonding of the pressure-sensitive adhesive sheet and the test plate. In general, the property for removing a paste decreases with a decreasing tackiness. However, the present invention can markedly decrease damage of the screen printing plate while

maintaining the property for removing a paste at high level, since the tackiness of the pressure-sensitive adhesive layer is reduced by the addition or formation of the fine particles.

According to the invented sheet 5 for removal of a solvent-containing substance and removing method 5, the pressure-sensitive adhesive layer has a decreased apparent tackiness due to the presence of the fine particles in the pressure-sensitive adhesive layer even if the

The pressure-sensitive adhesive sheet can therefore peel off a solvent-containing substance such as a paste turned about the back of a screen printing plate from an article to be cleaned such as the screen printing plate with an appropriate force, while maintaining the property for removing the solvent-containing substance. Thus, the pressure-sensitive adhesive sheet does not damage the article to be cleaned.

In the invented sheet 6 for removal of a solvent-containing substance, when a pressure-sensitive adhesive layer is formed on a substrate, the configuration of the pressure-sensitive adhesive layer is the same as in those mentioned above. The tackiness (adhesive strength) of the pressure-sensitive adhesive layer can be appropriately set in consideration of the property for removing the solvent-containing substance and the peeling property of the pressure-sensitive adhesive sheet from the article to be

treated (article to be cleaned), depending on the application thereof. The tackiness is preferably from about 10 to about 400 cN/25-mm, and more preferably from about 20 to about 350 cN/25-mm as determined by the method in conformity with JIS  
5 Z 0237, in which a SUS 430BA plate is used as a test plate, and the tackiness is measured after 1-minute contact-bonding of the pressure-sensitive adhesive sheet and the test plate.

When a foam layer is formed on a substrate in the invented sheet 6 for removal of a solvent-containing substance, resins for constituting the foam layer are not specifically limited as far as they are foamable resins. Such resins include, for example, rubbers, acrylic resins, urethane resins, olefinic resins, silicone resins, vinyl ether resins, styrenic resins, vinyl chloride resins, phenolic resins, urea resins, and epoxy resins. Among these resins, preferred are tacky resins such as rubbers (e.g., natural rubbers, styrene-butadiene copolymer rubbers, polyisobutylenes, butyl rubbers, reclaimed rubbers, rubber latex, styrene-isoprene-styrene block copolymers, polybutadienes, chloroprene rubbers, and  
10 acrylic rubbers), acrylic resins (e.g., acrylic resins each mainly containing a C<sub>2</sub>-C<sub>10</sub> alkyl acrylate as a base monomer and having Tg of from about -20°C to about -70°C; and styrene-acrylic ester copolymers), urethane resins, olefinic resins (e.g., polyethylenes; polypropylenes;  
15 ethylene-propylene copolymers, ethylene-vinyl acetate

copolymers, ethylene-acrylic ester copolymers, and other ethylenic copolymers), and silicone resins. The resins may be crosslinked. Each of these resins can be used alone or in combination.

5       The expansion ratio of the foam layer depends on the type of the resin and the process of foaming and is, for example, from about 1.2 to about 100 times. The foam layer may further comprise various additives such as plasticizers, antioxidants, flame retarders, UV absorbers, coloring agents, fillers, pressure-sensitive adhesives, tackifiers, and crosslinking agents.

9  
9  
9  
9  
9  
9  
9  
9  
9  
9  
10     The thickness of the foam layer can be appropriately selected within a range not deteriorating the strength and workability and is, for example, from about 0.05 to about 5 mm, and preferably from about 0.1 to about 2 mm. The sheet may further comprise a primer coat or other additional layers between the substrate and the foam layer. The foam layer may be formed on both sides of the substrate.

15     A surface of the foam layer preferably has such a tackiness that the sheet can adhere to an article to be treated such as a screen printing plate and can be easily peeled off from the article without significant resistance. In a preferred embodiment, the surface of the foam layer has a tackiness of, for example, from about 1 to 200 cN/25-mm as determined by the method in conformity with JIS Z 0237, in

which a SUS 430BA plate is used as a test plate, and the tackiness is measured after 1-minute contact-bonding of the pressure-sensitive adhesive sheet and the test plate. The tackiness can be controlled by appropriately selecting the 5 type of the resin constituting the foam layer, and the types and amounts of incorporated additives.

Of the invented sheets 6 for removal of a solvent-containing substance, the removing sheet having the foam layer on a substrate can be prepared by conventional foaming techniques such as extrusion foaming and injection foaming. Alternatively, the sheet can be prepared by applying a mixture containing a resin to constitute the foam layer and an appropriate foaming agent to a substrate, and heating and foaming the applied mixture. A foaming process 10 can be appropriately selected, for example, depending on the type of the resin, from any processes. Such processes include 15 a process in which the mixture is foamed by mechanical agitation (mechanical foaming), a process using a gas produced as a result of reaction, a process using a foaming agent (a volatile foaming agent or decomposable foaming agent), a process in which a soluble substance is removed, a process of foaming the mixture by spraying, a process in which a syntactic foam is formed, and a sintering process.

An important feature of the invented sheet 6 for removal 20 of a solvent-containing substance is that the sheet for

removal of a solvent-containing substance as mentioned above has been subjected to antistatic treatment. Processes for subjecting the sheet to antistatic treatment are not specifically limited and include, for example, (i) processes  
5 in which an electrically conductive layer is formed in at least one region selected from a surface on the substrate side, a surface on the pressure-sensitive adhesive layer side or foam layer side, and an interface between the substrate and the pressure-sensitive adhesive layer or foam layer, (ii)  
10 processes in which an agent for imparting electrical conductivity (e.g., an antistatic agent or electrically conductive substance) is added to a material constituting the substrate, (iii) processes in which a material itself constituting the substrate is composed of an electrically  
15 conductive substance, and (iv) processes in which an agent for imparting electrical conductivity (e.g., an antistatic agent or electrically conductive substance) is added to the pressure-sensitive adhesive layer or foam layer.

The processes (i) include, for example, a process in which  
20 a thin film layer of a metal, metal oxide or another electrically conductive substance is formed on a surface of, for example, the substrate by electroplating, electroless plating, vacuum deposition, sputtering, or ion plating; a process in which a metallic foil is laminated onto, for example,  
25 the substrate to thereby form a metal thin film layer; and a

process in which a coat of a composition containing an agent for imparting electrical conductivity is applied to a surface of, for example, the substrate. The thickness of the electrically conductive layer can be appropriately set, for 5 example, depending on the process for the formation of the electrically conductive layer.

The processes (ii) include, for example, a process in which an agent for imparting electrical conductivity is kneaded into a material constituting the substrate; and a 10 process in which a material constituting the substrate is impregnated with a solution or dispersion containing an agent for imparting electrical conductivity. The processes (iii) include, for example, a process in which the substrate is composed of a metallic foil (e.g., a foil of copper, aluminium, 15 nickel, iron, lead or silver). The processes (iv) include, for example, a resin composition containing a resin for constituting the pressure-sensitive adhesive layer or foam layer and an agent for imparting electrical conductivity is subjected to a conventional molding to thereby form the 20 pressure-sensitive adhesive layer or foam layer; and a process in which an electrically conductive polymer is used as a resin for constituting the pressure-sensitive adhesive layer or foam layer.

Such agents for imparting electrical conductivity 25 include, but are not limited to, copper, nickel, aluminium,

iron, chromium, cobalt, antimony, molybdenum, silver,  
platinum, gold, and other metals or alloys of these metals  
(e.g., fine powders or fibers); carbon black and other carbons  
(e.g., powders or fibers); electrically conductive tin oxide,  
5 silica, zinc oxide and other inorganic oxides such as metal  
oxides; anionic antistatic agents (e.g., alkyl sulfate  
antistatic agents, alkyl aryl sulfate antistatic agents,  
alkyl phosphate antistatic agents, and alkylamine sulfate  
antistatic agents), cationic antistatic agents (e.g.,  
10 quaternary ammonium salt antistatic agents, quaternary  
ammonium resin antistatic agents, and imidazoline antistatic  
agents), nonionic antistatic agents (e.g., sorbitan  
antistatic agents, ether antistatic agents, amine and amide  
antistatic agents, ethanolamide antistatic agents, and  
15 polyethylene glycol antistatic agents), amphoteric  
antistatic agents (e.g., betaine antistatic agents), and  
other surfactant-based antistatic agents; TCNQ  
(tetracyanoquinodimethane), polyene polymers (e.g.,  
polyacetylene), aromatic polymers [e.g., poly(p-phenylene)  
20 and poly(2,6-naphthalene)], heterocyclic polymers [e.g.,  
polypyrrole, poly(2,5-thienylene) and  
poly(pyridine-2,5-diyl)], hetero-chain polymers [e.g.,  
poly(phenylene sulfide) and polyaniline], copolymerized  
polymers [e.g., copoly(phenylene/vinylene) and  
25 poly(dithienylpolyene)], ladder polymers (e.g., polyacenes),

and other electrically conductive polymers (organic semiconductor polymers). Each of these agents for imparting electrical conductivity can be used alone or in combination.

The amount of the agent for imparting electrical conductivity can be appropriately selected depending on a process for subjecting the sheet for removal of a solvent-containing substance to antistatic treatment within a range not deteriorating film-forming property or other properties.

In the invented sheet 6 for removal of a solvent-containing substance, at least one (preferably both) of both sides of the sheet has a surface resistivity of preferably  $10^{13} \Omega$  or less (e.g., from about  $10^0 \Omega$  to about  $10^{13} \Omega$ ) and more preferably  $10^{11} \Omega$  or less (e.g., from about  $10^0 \Omega$  to about  $10^{11} \Omega$ ). The surface resistivity can be controlled by appropriately selecting, for example, the type and amount of the agent for imparting electrical conductivity.

According to the invented sheet 6 for removal of a solvent-containing substance and removing method 6, the pressure-sensitive adhesive layer or foam layer is formed at least on one side of the substrate, and the sheet can efficiently remove a solvent-containing substance by such an easy operation that the sheet is stuck to or pressed to and peeled off from the solvent-containing substance. Such solvent-containing substances include, for example, a paste

- (an ink) for use in screen printing or an ink deposited on a roll of a printing machine such as an offset printing machine. Additionally, the sheet has been subjected to antistatic treatment and can therefore prevent electrostatic buildup.
- 5 Consequently, there is no need of static eliminators, malfunctions caused by static electricity are avoided, and yields and operating ratio of facilities are improved.

#### Industrial Applicability

10 The invented sheets for removal of a solvent-containing substance can be used for cleaning of articles carrying deposited solvent-containing substances (specifically, semisolid substances). Such solvent-containing substances include, for example, a paste (an ink) deposited on a screen printing plate, an ink deposited on a roll of a printing machine such as an offset printing machine, an ink stain in the vicinity of an ink jet orifice of an ink jet printer, and a paint deposited on an article, floor or wall. The sheets are specifically suitable as cleaning sheets for removal of

15  
20 a paste (an ink) turned about the back of a screen printing plate.

According to the invented sheets for removal of a solvent-containing substance and removing methods, the sheets can reliably adhere to and remove solvent-containing substances and can highly efficiently remove these

solvent-containing substances. Such solvent-containing substances include, for example, a paste turned about the back of a screen printing plate, an ink remained in a blanket cylinder of an offset printing machine, and an ink stain in  
5 the vicinity of an ink jet orifice of an ink jet printer.

In the invented sheet for removal of a solvent-containing substance and removing method, the pressure-sensitive adhesive layer can absorb at least a predetermined amount of a solvent and has extra absorptivity of the solvent, and the sheets can reliably adhere to and remove a solvent-containing substance deposited on an article to be treated, such as a  
10 paste turned about the back of a screen printing plate.

According to the invented sheet for removal of a solvent-containing substance and removing method, the pressure-sensitive adhesive layer can absorb at least a predetermined amount of a solvent in a short time and has a tackiness within a specific range after absorbing the solvent,  
15 and the sheet can reliably and efficiently adhere to and remove a solvent-containing substance deposited on an article to be treated, such as a paste turned about the back of a screen printing plate. The invented sheet and removing method can therefore reduce imperfect printing due to bleeding in screen printing, can shorten the time of cleaning for rolls to thereby improve productivity in offset printing, gravure printing and  
20 flexographic printing.  
25

The invented pressure-sensitive adhesive sheet and removing method have features in that the pressure-sensitive adhesive layer can absorb at least a predetermined amount of a solvent in a short time and that the components of the pressure-sensitive adhesive layer do not migrate into an adherend in a predetermined peel test after absorbing a predetermined amount of the solvent. Accordingly, the sheet and removing method can efficiently remove a solvent-containing substance deposited on an article to be treated and can avoid contamination or stain of a surface of the article to be treated with the components of the pressure-sensitive adhesive layer after removal of the solvent-containing substance. When, for example, a paste turned about the back of a screen printing plate is removed, a printed matter is not stained to thereby increase yields in printing.

According to the invented pressure-sensitive adhesive sheet for removal of a solvent-containing substance and removing method, the solubility parameter of a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet is in a specific relation with the solubility parameter of a solvent contained in the solvent-containing substance to be removed, and the invented cleaning sheet therefore can rapidly absorb the solvent and can maintain its

tackiness. Accordingly, the pressure-sensitive adhesive sheet can reliably adhere to and remove solvent-containing substances deposited on, for example, machines or floors, without broadening stains toward surroundings and without

5 damaging the article to be cleaned. Additionally, the invented sheet and removing method can easily clean an article to be cleaned without damaging the article and without broadening stains toward surroundings and can be applied to a wide variety of articles to be cleaned and

10 solvent-containing substances (deposits) to be removed. The invented pressure-sensitive adhesive sheet and removing method can therefore realize cleaning operations using pressure-sensitive adhesive sheets in printing and painting processes, which cleaning operations have been performed only by wiping with wastes (wiping rags). The invented removing method can rapidly select and use an optimum pressure-sensitive adhesive sheet depending on the type of a solvent contained in the solvent-containing substance deposited on an article to be cleaned, without subjecting a  
15 variety of pressure-sensitive adhesive sheets to actual testing.

20 In the invented pressure-sensitive adhesive sheet for removal of a solvent-containing substance and removing method, the pressure-sensitive adhesive layer comprises fine particles. Accordingly, the pressure-sensitive adhesive

sheet can have an appropriately controlled tackiness, can satisfactorily remove a solvent-containing substance such as a paste turned about the back of a screen printing plate and can peel off the solvent-containing substance without  
5 damaging an article to be cleaned such as the screen printing plate.

The invented sheet for removal of a solvent-containing substance and removing method can efficiently remove a solvent-containing substance such as a paste turned about the back of a screen printing plate while preventing electrostatic buildup. Consequently, there is no need of static eliminators, malfunctions caused by static electricity are avoided, and yields and operating ratio of facilities are improved.

15

#### EXAMPLES

The present invention will be illustrated in further detail with reference to several examples below, which are not intended to limit the scope of the invention. Figures within  
20 parentheses after the name of a solvent in Examples 13 and 14 are solubility parameters (SPs) [ $(J/cm^3)^{1/2}$ ].

##### EXAMPLE 1

A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a  
25 thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene

film (substrate) 0.06 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2) and 15 parts by weight of an isocyanate crosslinking agent.

The pressure-sensitive adhesive sheet before use had a tackiness (adhesive strength) of 140 cN/25-mm as determined by the method in conformity with JIS Z 0237, in which a SUS 430BA plate was used as a test plate, and the tackiness was measured after 1-minute contact-bonding of the pressure-sensitive adhesive sheet with the test plate.

The above-prepared pressure-sensitive adhesive sheet was cut to a size of 30 mm times 30 mm (30 mm x 30 mm), was weighed, was immersed in a solvent [diethylene glycol monobutyl ether acetate/diethylene glycol monobutyl ether (weight ratio: 9/1)] for 3 minutes, was taken out from the solvent, the solvent deposited on a surface of the sheet was immediately wiped off with a waste rag, the sheet was then weighed again, and the solvent absorption per unit area was calculated to find to be 35 g/m<sup>2</sup>.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a

plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the screen printing plate and could fully remove the turned-about paste.

5        EXAMPLE 2

A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a thickness after drying of 5 µm to one side of a polypropylene/polyethylene (weight ratio: 90/10) blend film (substrate) 0.04 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2), 7 parts by weight of a terpene phenol tackifier, 3 parts by weight of an isocyanate crosslinking agent, and 1 part by weight of a phosphate surfactant.

The tackiness before use and solvent absorption of the above-prepared pressure-sensitive adhesive sheet were 150 cN/25-mm and 33 g/m<sup>2</sup>, respectively, as determined in the same manner as in Example 1.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a

plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the screen printing plate and could fully remove the turned-about paste.

5           EXAMPLE 3

A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a thickness after drying of 10 µm to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylic acid) (weight ratio: 96/4) and 15 parts by weight of an isocyanate crosslinking agent.

10           The tackiness before use and solvent absorption of the above-prepared pressure-sensitive adhesive sheet were 180 cN/25-mm and 25 g/m<sup>2</sup>, respectively, as determined in the same manner as in Example 1.

15           The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be satisfactorily 20 peeled off from the screen printing plate and could fully 25

remove the turned-about paste.

EXAMPLE 4

A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2) and 0.5 part by weight of an epoxy crosslinking agent.

The tackiness before use and solvent absorption of the above-prepared pressure-sensitive adhesive sheet were 140 cN/25-mm and 28 g/m<sup>2</sup>, respectively, as determined in the same manner as in Example 1.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the screen printing plate and could fully remove the turned-about paste.

COMPARATIVE EXAMPLE 1

A pressure-sensitive adhesive sheet was prepared by

applying an acrylic pressure-sensitive adhesive to a thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic

5 pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/ acrylic acid) (weight ratio: 96/4), 8 parts by weight of a rosin tackifier, and 2 parts by weight of an epoxy crosslinking agent.

9 10 The tackiness before use and solvent absorption of the above-prepared pressure-sensitive adhesive sheet were 110  
9 cN/25-mm and 15 g/ $\text{m}^2$ , respectively, as determined in the same  
9 manner as in Example 1.  
9  
9

9 15 The pressure-sensitive adhesive sheet was then stuck to  
9 and peeled off from the back of a screen printing plate, which  
9 had been used a predetermined number of times and carried a  
9 paste (a fluorescent paste for use in the manufacture of a  
9 plasma display panel) turned about the back. As a result, the  
9 pressure-sensitive adhesive sheet could be peeled off from the  
9 screen printing plate without problems, but the paste was  
20 remained on the back of the screen printing plate.  
9

#### COMPARATIVE EXAMPLE 2

A pressure-sensitive adhesive sheet was prepared by applying polyisobutylene as a pressure-sensitive adhesive to a thickness after drying of 7  $\mu\text{m}$  to one side of a  
25 polypropylene/polyethylene (weight ratio: 90/10) blend film

(substrate) 0.04 mm thick, and drying the applied pressure-sensitive adhesive.

The tackiness before use and solvent absorption of the above-prepared pressure-sensitive adhesive sheet were 500  
5 cN/25-mm and 1 g/m<sup>2</sup>, respectively, as determined in the same manner as in Example 1.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be neither satisfactorily peeled off from the screen printing plate nor sufficiently remove the turned-about paste.

15 EXAMPLE 5

A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a thickness after drying of 10 µm to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic  
20 pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2) and 15 parts by weight of an isocyanate crosslinking agent.

25 The tackiness before use of the pressure-sensitive

adhesive sheet was 140 cN/25-mm (140 gf/25-mm) as determined by the method in conformity with JIS Z 0237, in which a SUS 430BA plate was used as a test plate and the tackiness was measured after 1-minute contact-bonding of the

5 pressure-sensitive adhesive sheet and the test plate. The above-prepared pressure-sensitive adhesive sheet was cut to a size of 30 mm times 30 mm (30 mm x 30 mm), was weighed, was immersed in a solvent [diethylene glycol monobutyl ether acetate/diethylene glycol monobutyl ether (weight ratio:

10 9/1)] for 1 second, was taken out from the solvent, the solvent deposited on a surface of the sheet was immediately wiped off with a waste rag, the sheet was then weighed again, and the solvent absorption per unit area was calculated to find to be 10 g/m<sup>2</sup>. Separately, 5 g/m<sup>2</sup> of the solvent was applied to a

15 poly(ethylene terephthalate) film using a wire bar, the pressure-sensitive adhesive sheet having the same size as above was stuck to the film carrying the solvent to thereby permit the pressure-sensitive adhesive layer of the

pressure-sensitive adhesive sheet to absorb 5 g/m<sup>2</sup> of the

20 solvent, and the tackiness of the pressure-sensitive adhesive sheet was then determined in the same manner as above to find to be 5 cN/25-mm (5 gf/25-mm).

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which  
25 had been used a predetermined number of times and carried a

5        paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the screen printing plate and could fully remove the turned-about paste.

EXAMPLE 6

9        A pressure-sensitive adhesive sheet was prepared by  
10      applying an acrylic pressure-sensitive adhesive to a thickness after drying of 5  $\mu\text{m}$  to one side of a polypropylene/polyethylene (weight ratio: 90/10) blend film  
15      (substrate) 0.04 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2), 7 parts by weight of a terpene phenol tackifier, 3 parts by weight of an isocyanate crosslinking agent, and 1 part by weight of a phosphate surfactant.

20      The tackiness before use, solvent absorption and tackiness after absorbing the solvent of the above-prepared pressure-sensitive adhesive sheet were 150 cN/25-mm (150 gf/25-mm), 17 g/m<sup>2</sup> and 3 cN/25-mm (3 gf/25-mm), respectively, as determined in the same manner as in Example 5.

25      The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which

had been used a predetermined number of times and carried a  
paste (a fluorescent paste for use in the manufacture of a  
plasma display panel) turned about the back. As a result, the  
pressure-sensitive adhesive sheet could be satisfactorily  
5 peeled off from the screen printing plate and could fully  
remove the turned-about paste.

EXAMPLE 7

A pressure-sensitive adhesive sheet was prepared by  
applying an acrylic pressure-sensitive adhesive to a  
10 thickness after drying of 15  $\mu\text{m}$  to one side of a polyethylene  
film (substrate) 0.06 mm thick, and drying the applied acrylic  
pressure-sensitive adhesive. The acrylic  
pressure-sensitive adhesive was composed of 100 parts by  
weight of a copoly(2-ethylhexyl acrylate/vinyl  
15 acetate/acrylic acid) (weight ratio: 60/30/5), 30 parts by  
weight of a terpene phenol tackifier, 7 parts by weight of an  
isocyanate crosslinking agent, and 1 part by weight of a  
phosphate surfactant.

The tackiness before use, solvent absorption and  
20 tackiness after absorbing the solvent of the above-prepared  
pressure-sensitive adhesive sheet were 130 cN/25-mm (130  
gf/25-mm), 19 g/m<sup>2</sup> and 31 cN/25-mm (32 gf/25-mm), respectively,  
as determined in the same manner as in Example 5.

The pressure-sensitive adhesive sheet was then stuck to  
25 and peeled off from the back of a screen printing plate, which

had been used a predetermined number of times and carried a  
paste (a fluorescent paste for use in the manufacture of a  
plasma display panel) turned about the back. As a result, the  
pressure-sensitive adhesive sheet could be satisfactorily  
5 peeled off from the screen printing plate and could fully  
remove the turned-about paste.

#### COMPARATIVE EXAMPLE 3

A pressure-sensitive adhesive sheet was prepared by  
applying an acrylic pressure-sensitive adhesive to a  
10 thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene  
film (substrate) 0.06 mm thick, and drying the applied acrylic  
pressure-sensitive adhesive. The acrylic  
pressure-sensitive adhesive was composed of 100 parts by  
weight of a copoly(butyl acrylate/acrylic acid) (weight  
15 ratio: 96/4), 8 parts by weight of a rosin tackifier, and 5  
parts by weight of an epoxy crosslinking agent.

The tackiness before use, solvent absorption and  
tackiness after absorbing the solvent of the above-prepared  
pressure-sensitive adhesive sheet were 110 cN/25-mm (110  
20 gf/25-mm), 9 g/m<sup>2</sup> and 0 cN/25-mm (0 gf/25-mm), respectively,  
as determined in the same manner as in Example 5.

The pressure-sensitive adhesive sheet was then stuck to  
and peeled off from the back of a screen printing plate, which  
had been used a predetermined number of times and carried a  
25 paste (a fluorescent paste for use in the manufacture of a

plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be peeled off from the screen printing plate without problems, but the paste was remained on the back of the screen printing plate.

5           COMPARATIVE EXAMPLE 4

A pressure-sensitive adhesive sheet was prepared by applying polyisobutylene as a pressure-sensitive adhesive to a thickness after drying of 7  $\mu\text{m}$  to one side of a polypropylene/polyethylene (weight ratio: 90/10) blend film (substrate) 0.04 mm thick, and drying the applied pressure-sensitive adhesive.

The tackiness before use, solvent absorption and tackiness after absorbing the solvent of the above-prepared pressure-sensitive adhesive sheet were 490 cN/25-mm (500 gf/25-mm), 1 g/m<sup>2</sup> and 0 cN/25-mm (0 gf/25-mm), respectively, as determined in the same manner as in Example 5.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could neither be satisfactorily peeled off from the screen printing plate nor sufficiently remove the turned-about paste.

25           EXAMPLE 8

A pressure-sensitive adhesive sheet was prepared in the same manner as in Example 5 and was then cut to a size of 30 mm times 30 mm (30 mm x 30 mm), was weighed, was immersed in a solvent [toluene/ethyl acetate/methyl ethyl ketone (weight ratio: 20/40/40)] for 1 second, was taken out from the solvent, the solvent deposited on a surface of the sheet was immediately wiped off with a waste rag, the sheet was then weighed again, and the solvent absorption per unit area was calculated to find to be 15 g/m<sup>2</sup>. Separately, 5 g/m<sup>2</sup> of the solvent was applied to a poly(ethylene terephthalate) film using a wire bar, the pressure-sensitive adhesive sheet having the same size as above was stuck to the film carrying the solvent to thereby permit the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet to absorb 5 g/m<sup>2</sup> of the solvent, and the tackiness of the pressure-sensitive adhesive sheet was determined in the same manner as above to find to be 20 cN/25-mm.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from a plate cylinder of a gravure printing machine, which carried a remained ink containing the solvent. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the plate cylinder and could fully remove the ink.

EXAMPLE 9

A pressure-sensitive adhesive sheet was prepared in the

same manner as in Example 6. The solvent absorption and the tackiness after absorbing the solvent of the pressure-sensitive adhesive sheet were  $20 \text{ g/m}^2$  and  $5 \text{ cN}/25\text{-mm}$ , respectively, as determined in the same manner as in Example

5 8.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from a plate cylinder of a gravure printing machine in the same manner as in Example 8, which plate cylinder carried a remained ink containing the solvent. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the plate cylinder and could fully remove the ink.

#### EXAMPLE 10

A pressure-sensitive adhesive sheet was prepared in the same manner as in Example 7. The solvent absorption and the tackiness after absorbing the solvent of the pressure-sensitive adhesive sheet were  $30 \text{ g/m}^2$  and  $43 \text{ cN}/25\text{-mm}$ , respectively, as determined in the same manner as in Example 8.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from a plate cylinder of a gravure printing machine in the same manner as in Example 8, which plate cylinder carried a remained ink containing the solvent. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the plate cylinder and could

fully remove the ink.

COMPARATIVE EXAMPLE 5

A pressure-sensitive adhesive sheet was prepared in the same manner as in Comparative Example 3. The solvent

5 absorption and the tackiness after absorbing the solvent of the pressure-sensitive adhesive sheet were  $15 \text{ g/m}^2$  and 0 cN/25-mm, respectively, as determined in the same manner as in Example 8.

The pressure-sensitive adhesive sheet was then stuck to  
10 and peeled off from a plate cylinder of a gravure printing machine in the same manner as in Example 8, which plate cylinder carried a remained ink containing the solvent. As a result, the pressure-sensitive adhesive sheet could be peeled off from the plate cylinder without problems, but the  
15 ink was remained on the plate cylinder.

EXAMPLE 11

A pressure-sensitive adhesive sheet was prepared in the same manner as in Comparative Example 4. The solvent absorption and the tackiness after absorbing the solvent of  
20 the pressure-sensitive adhesive sheet were  $7 \text{ g/m}^2$  and 5 cN/25-mm, respectively, as determined in the same manner as in Example 8.

The pressure-sensitive adhesive sheet was then stuck to  
and peeled off from a plate cylinder of a gravure printing  
25 machine in the same manner as in Example 8, which plate

cylinder carried a remained ink containing the solvent. As a result, the pressure-sensitive adhesive sheet could be satisfactorily peeled off from the plate cylinder and could fully remove the ink.

5           EXAMPLE 12

A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2) and 15 parts by weight of an isocyanate crosslinking agent.

15           The above-prepared pressure-sensitive adhesive sheet was cut to a size of 30 mm times 30 mm (30 mm  $\times$  30 mm), was weighed, was immersed in a solvent [diethylene glycol monobutyl ether acetate/diethylene glycol monobutyl ether (weight ratio: 9/1)] for 1 second, was taken out from the solvent, the solvent deposited on a surface of the sheet was immediately wiped off with a waste rag, the sheet was then weighed again, and the solvent absorption per unit area was calculated to find to be 10 g/ $\text{m}^2$ . Separately, 5 g/ $\text{m}^2$  of the solvent was applied to a poly(ethylene terephthalate) film using a wire bar, the 20 pressure-sensitive adhesive sheet having the same size as

above was stuck to the film carrying the solvent to thereby permit the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet to absorb 5 g/m<sup>2</sup> of the solvent, the pressure-sensitive adhesive sheet was then stuck

5 to a stainless steel plate (a SUS 430BA plate) by a reciprocating motion of a 2-kg rubber roller and was peeled off without delay. As a result, no stain was observed in the stainless steel plate.

The pressure-sensitive adhesive sheet was then stuck to  
10 and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be satisfactorily  
15 peeled off from the screen printing plate and could fully remove the turned-back paste without any stain observed in the screen printing plate.

#### EXAMPLE 13

A pressure-sensitive adhesive sheet was prepared by  
20 applying an acrylic pressure-sensitive adhesive to a thickness after drying of 5 µm to one side of a polypropylene/polyethylene (weight ratio: 90/10) blend film (substrate) 0.04 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic  
25 pressure-sensitive adhesive was composed of 100 parts by

weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2), 7 parts by weight of a terpene phenol tackifier, and 3 parts by weight of an isocyanate crosslinking agent.

5       The solvent absorption of the pressure-sensitive adhesive sheet was 17 g/m<sup>2</sup> as determined in the same manner as in Example 12. After permitting the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet to absorb 5 g/m<sup>2</sup> of the solvent, the pressure-sensitive adhesive sheet was stuck to a stainless steel plate (a SUS 430BA plate) by a reciprocating motion of a 2-kg rubber roller and was peeled off without delay in the same manner as in Example 12. As a result, no stain was observed in the stainless steel plate.

10      15     The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could fully remove the turned-back paste without any stain observed in the screen printing plate.

#### COMPARATIVE EXAMPLE 6

20      A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a

thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylic acid) (weight ratio: 96/4) and 5 parts by weight of an epoxy crosslinking agent.

The solvent absorption of the pressure-sensitive adhesive sheet was 9 g/ $\text{m}^2$  as determined in the same manner as in Example 12. After permitting the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet to absorb 5 g/ $\text{m}^2$  of the solvent, the pressure-sensitive adhesive sheet was stuck to a stainless steel plate (a SUS 430BA plate) by a reciprocating motion of a 2-kg rubber roller and was peeled off without delay in the same manner as in Example 12. As a result, a stain was observed in the stainless steel plate.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could be peeled off from the screen printing plate without problems, but the paste was remained on the back of the screen printing plate.

A pressure-sensitive adhesive sheet was prepared by applying polyisobutylene as a pressure-sensitive adhesive to a thickness after drying of 7  $\mu\text{m}$  to one side of a polypropylene/polyethylene (weight ratio: 90/10) blend film (substrate) 0.04 mm thick, and drying the applied pressure-sensitive adhesive.

The solvent absorption of the pressure-sensitive adhesive sheet was 1 g/ $\text{m}^2$  as determined in the same manner as in Example 12. After permitting the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet to absorb 5 g/ $\text{m}^2$  of the solvent, the pressure-sensitive adhesive sheet was stuck to a stainless steel plate (a SUS 430BA plate) by a reciprocating motion of a 2-kg rubber roller and was peeled off without delay in the same manner as in Example 12. As a result, a stain was observed in the stainless steel plate.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could not sufficiently remove the turned-about paste.

#### COMPARATIVE EXAMPLE 8

A pressure-sensitive adhesive sheet was prepared by applying an acrylic pressure-sensitive adhesive to a

thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2).

The solvent absorption of the pressure-sensitive adhesive sheet was 40 g/m<sup>2</sup> as determined in the same manner as in Example 12. After permitting the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet to absorb 5 g/m<sup>2</sup> of the solvent, the pressure-sensitive adhesive sheet was stuck to a stainless steel plate (a SUS 430BA plate) by a reciprocating motion of a 2-kg rubber roller and was peeled off without delay in the same manner as in Example 12. As a result, a stain was observed in the stainless steel plate. The stain was analyzed to find to be a mixture of the solvent and the pressure-sensitive adhesive polymer.

The pressure-sensitive adhesive sheet was then stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. As a result, the pressure-sensitive adhesive sheet could remove the turned-about paste without problems, but a stain was observed in the screen printing plate. The stain was analyzed to find

to be the pressure-sensitive adhesive polymer swelled by action of the solvent.

EXAMPLE 14

(1) Determination of Solubility Parameter (SP)  $\delta_1$  of

5 Pressure-sensitive Adhesive

A cleaning sheet was prepared by forming a pressure-sensitive adhesive layer 10  $\mu\text{m}$  thick on one side of a polyethylene film (substrate) 0.06 mm thick. The pressure-sensitive adhesive layer was composed of an acrylic pressure-sensitive adhesive containing 100 parts by weight of a copoly(butyl acrylate/acrylic acid) (weight ratio: 95/5) and 15 parts by weight of an isocyanate crosslinking agent.

About 0.5 g of each of samples obtained by cutting the pressure-sensitive adhesive of the cleaning sheet was accurately weighed, and the weighed samples were immersed respectively in n-heptane (15.1), cyclohexane (16.8), toluene (18.1), ethyl acetate (18.6), methyl ethyl ketone (19.0), cyclohexanone (20.3), and isobutyl alcohol (21.5) at room temperature for 7 days. The degree of swelling (%) and gel fraction (%) of the pressure-sensitive adhesive constituting the pressure-sensitive layer in each sample were determined according to the aforementioned procedure. The results are shown in Table 1.

Table 1

Solvent	n-Heptane	Cyclohexane	Toluene	Ethyl acetate
SP	15.1	16.8	18.1	18.6
[ (J/cm <sup>3</sup> ) <sup>1/2</sup> ]				
Degree of Swelling	245	293	976	1420
(%)				
Gel	97.8	98.0	86.7	81.4
Fraction				
(%)				

Table 1-continued

Solvent	Methyl ethyl ketone	Cyclohexanone	Isobutyl alcohol
SP	19.0	20.3	21.5
[ $(J/cm^3)^{1/2}$ ]			
Degree of Swelling (%)	1440	973	347
Gel	78.5	99.8	99.0
Fraction (%)			

Table 1 shows that the solubility parameter (SP) (typical) of the pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer of cleaning sheet was defined as 19.0 [(J/cm<sup>3</sup>)<sup>1/2</sup>] (i.e., SP of a solvent in which the pressure-sensitive adhesive exhibited the maximum degree of swelling).

(2) Determination of Tackiness (180 degree peel strength)

About 5 g/m<sup>2</sup> of each of the following seven high boiling

solvents was applied onto a surface of a substrate [a poly(ethylene terephthalate) (PET) film 38  $\mu\text{m}$  thick] using a Meyer bar #04, and the above-prepared cleaning sheet was stuck thereto, and the peel strength was determined according to the method described in JIS Z 0237, in which a stainless steel plate (a SUS 430 BA plate) was used as an adherend and the peel strength was measured after 1-minute contact-bonding of the cleaning sheet and the adherend. The results are shown in Table 2.

Used solvents: dodecane (16.2), decahydronaphthalene (18.0), diethyl phthalate (18.2), diethylene glycol monobutyl ether acetate (19.2), dibenzyl ether (20.5), diethylene glycol monobutyl ether (21.5), and 1,4-butanediol (24.8)

Table 2

Solvent	Dodecane	Decahydro-naphthalene	Diethyl phthalate	Diethylene glycol monobutyl ether acetate
SP	16.2	18.0	18.2	19.2
$[(J/cm^3)^{1/2}]$				
180° Peel strength (cN/20 mm)	0.5	4	5	5

Table 2-continued

Solvent	Dibenzyl ether	Diethylene glycol monobutyl ether	1,4-Butanediol
SP	20.5	21.5	24.8
$[(J/cm^3)^{1/2}]$			
180° Peel strength (cN/20 mm)	9	8	0

Table 2 shows that, when the cleaning sheet was stuck to a region wetted with a solvent having a solubility parameter within a range of  $\pm 4$   $[(J/cm^3)^{1/2}]$  with respect to the solubility parameter (SP) ( $=19.0$   $[(J/cm^3)^{1/2}]$ ) of the pressure-sensitive adhesive of the pressure-sensitive adhesive layer of the cleaning sheet, the cleaning sheet after sticking exhibited a tackiness exceeding 0, indicating that the tackiness was maintained. Accordingly, this cleaning sheet can effectively clean off deposits containing solvents having solubility parameters within the above range.

## EXAMPLE 15

(1) Determination of Solubility Parameter (SP)  $\delta_1$  of

## 15 Pressure-sensitive Adhesive

A cleaning sheet was prepared by forming a pressure-sensitive adhesive layer 10  $\mu\text{m}$  thick composed of

polyisobutylene on one side of a polyethylene film (substrate) 0.06 mm thick.

Using the above-prepared cleaning sheet, the degree of swelling (%) and gel fraction (%) were determined according 5 to the aforementioned procedure. The results are shown in Table 3.

Table 3

Solvent	n-Heptane	Cyclohexane	Toluene	Ethyl acetate
SP	15.1	16.8	18.1	18.6
$[(J/cm^3)^{1/2}]$				
Degree of Swelling (%)	870	1190	890	715
Gel Fraction (%)	63.0	64.0	65.5	69.5

Table 3-continued

Solvent	Methyl ethyl ketone	Cyclohexanone	Isobutyl alcohol
SP	19.0	20.3	21.5
$[(J/cm^3)^{1/2}]$			
Degree of Swelling (%)	688	700	770
Gel Fraction (%)	70.8	92.0	94.0

Table 3 shows that the solubility parameter (SP) 10 (typical) of the pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer of the cleaning sheet was defined as 16.8  $[(J/cm^3)^{1/2}]$  (i.e., SP of a solvent in which the pressure-sensitive adhesive exhibited the maximum degree of swelling).

15 (2) Determination of Tackiness (180 degree peel strength)

of Cleaning Sheet

The tackiness (180 degree peel strength) of the cleaning sheet was determined in the same manner as in Example 14. The results are shown in Table 4.

Table 4

Solvent	Dodecane	Decahydro-naphthalene	Diethyl phthalate	Diethylene glycol monobutyl ether acetate
SP	16.2	18.0	18.2	19.2
[(J/cm <sup>3</sup> ) <sup>1/2</sup> ]				
180° Peel strength (cN/20-mm)	3	1	1	0.5

Table 4-continued

Solvent	Dibenzyl ether	Diethylene glycol monobutyl ether	1,4-Butanediol
SP	20.5	21.5	24.8
[(J/cm <sup>3</sup> ) <sup>1/2</sup> ]			
180° Peel strength (cN/20-mm)	0.5	0	0

Table 4 shows that, when the cleaning sheet was stuck to a region wetted with a solvent having a solubility parameter within a range of  $\pm 4$   $[(J/cm^3)^{1/2}]$  with respect to the solubility parameter (SP) ( $=16.8$   $[(J/cm^3)^{1/2}]$ ) of the pressure-sensitive adhesive of the pressure-sensitive adhesive layer of the cleaning sheet, the cleaning sheet after sticking exhibited a tackiness exceeding 0, indicating that the tackiness (adhesion) was maintained. Accordingly, this cleaning sheet can effectively clean off deposits containing solvents having solubility parameters within the above range.

EXAMPLE 16

A pressure-sensitive adhesive sheet was prepared by applying a pressure-sensitive adhesive composition to a thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied pressure-sensitive adhesive composition. The pressure-sensitive adhesive composition was composed of 100 parts by weight of an acrylic polymer [a copoly(butyl acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2)] and 20 parts by weight of dispersed fine particles of poly(methyl methacrylate) having a mean particle size of from 1 to 2  $\mu\text{m}$ .

The tackiness of the pressure-sensitive adhesive sheet was 2.3 N/25-mm as determined by the method in conformity with JIS Z 0237, in which a SUS 430BA plate was used as a test plate and the tackiness was measured after 1-minute contact-bonding of the pressure-sensitive adhesive sheet and the test plate.

#### EXAMPLE 17

A pressure-sensitive adhesive sheet was prepared by applying a pressure-sensitive adhesive composition to a thickness after drying of 10  $\mu\text{m}$  to one side of a polypropylene/polyethylene (weight ratio: 90/10) blend film (substrate) 0.04 mm thick, and drying the applied pressure-sensitive adhesive composition. The pressure-sensitive adhesive composition was composed of 100 parts by weight of an acrylic copolymer [a copoly(butyl

acrylate/acrylonitrile/acrylic acid) (weight ratio: 90/10/2) and 17 parts by weight of an isocyanate crosslinking agent. The isocyanate crosslinking agent was not in the form of a fine particle, but a myriad of domains each having a size 5 of 0.01 micrometers to several micrometers was observed in the resulting pressure-sensitive adhesive layer.

The tackiness of the above-prepared pressure-sensitive adhesive sheet was 2.0 N/25-mm as determined in the same manner as in Example 16.

10 EXAMPLE 18

A pressure-sensitive adhesive sheet was prepared by applying a pressure-sensitive adhesive composition to a thickness after drying of 20  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied 15 pressure-sensitive adhesive composition. The pressure-sensitive adhesive composition was composed of 100 parts by weight of an acrylic polymer [a copoly(butyl acrylate/acrylic acid) (weight ratio: 96/4)] and 30 parts by weight of dispersed melamine fine particles having a mean 20 particle size of from 1 to 2  $\mu\text{m}$ .

The tackiness of the above-prepared pressure-sensitive adhesive sheet was 2.5 N/25-mm as determined in the same manner as in Example 16.

COMPARATIVE EXAMPLE 9

25 A pressure-sensitive adhesive sheet was prepared by

applying an acrylic polymer as a pressure-sensitive adhesive to a thickness after drying of 10  $\mu\text{m}$  to one side of a polyethylene film (substrate) 0.06 mm thick, and drying the applied acrylic polymer. The acrylic polymer was a  
5 copoly(butyl acrylate/acrylonitrile/acrylic acid (weight ratio: 90/10/2).

The tackiness of the above-prepared pressure-sensitive adhesive sheet was 5.0 N/25-mm as determined in the same manner as in Example 16.

10 COMPARATIVE EXAMPLE 10

A pressure-sensitive adhesive sheet was prepared by applying an acrylic polymer as a pressure-sensitive adhesive to a thickness after drying of 20  $\mu\text{m}$  to one side of a polypropylene/polyethylene (weight ratio: 90/10) blend film  
15 (substrate) 0.04 mm thick, and drying the applied acrylic polymer. The acrylic polymer was a copoly(butyl acrylate/acrylic acid) (weight ratio: 96/4).

The tackiness of the above-prepared pressure-sensitive adhesive sheet was 7.5 N/25-mm as determined in the same manner  
20 as in Example 16.

Evaluation Test

Each of the pressure-sensitive adhesive sheets obtained according to Examples 16 to 18 and Comparative Examples 9 and  
25 10 was stuck to and peeled off from the back of a screen printing plate, which had been used a predetermined number of

times and carried a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back. Whether be smoothly peeled off from the screen printing plate (releasability) and whether each pressure-sensitive adhesive sheet could satisfactorily remove the turned-about paste (removing property) were evaluated according to the following criteria. The results are shown in Table 5.

(1) Releasability from Screen Printing Plate

Good: The sheet could be easily peeled off without damaging the screen printing plate.

Poor: An emulsion of the screen printing plate was peeled off from the screen printing plate when the sheet was peeled off.

(2) Property for Removing Turned-about Paste

Good: The turned-about paste could be fully removed.

Poor: The turned-about paste could not be sufficiently removed.

Table 5

	Ex. 16	Ex. 17	Ex. 18	Com. Ex. 9	Com. Ex. 10
Tackiness (cN/25-mm)	230	200	250	500	750
Releasability*	good	good	good	poor	poor
Removing Property**	good	good	good	good	good

Releasability\*: Releasability from the screen printing plate

Removing Property\*\*: Property for removing the turned-about paste

## EXAMPLE 19

A cleaning pressure-sensitive adhesive sheet was prepared by applying an antistatic agent containing a nonionic surfactant to one side of a polyethylene film (substrate) 0.06 mm thick to thereby subject the side to antistatic treatment; applying an acrylic pressure-sensitive adhesive to the other side to a thickness after drying of 10 µm; and drying the applied acrylic pressure-sensitive adhesive. The acrylic pressure-sensitive adhesive was composed of 100 parts by weight of a copoly(butyl acrylate/acrylic acid (weight ratio: 95/5) and 15 parts by weight of an isocyanate crosslinking agent.

The tackiness before use of the above-prepared cleaning pressure-sensitive adhesive sheet was 1.4 N/25-mm as determined by the method in conformity with JIS Z 0237, in which a SUS 430BA plate was used as a test plate and the tackiness was measured after 1-minute contact-bonding of the pressure-sensitive adhesive sheet and the test plate. The surface resistivity (ASTM D-257) of the pressure-sensitive adhesive sheet on the antistatic-treated side was  $6 \times 10^9 \Omega$ .

## EXAMPLE 20

A cleaning pressure-sensitive adhesive sheet was prepared by evaporating aluminium as an electrically conductive substance to a thickness of 1000 angstroms onto one side of a polyester film (substrate) 0.05 mm thick; applying

an acrylic pressure-sensitive adhesive to a thickness after  
drying of 10  $\mu\text{m}$  to the other side of the polyethylene film;  
and drying the applied pressure-sensitive adhesive. The  
acrylic pressure-sensitive adhesive was composed of 100 parts  
5 by weight of a copoly(butyl acrylate/acrylic acid) (weight  
ratio: 95/5) and 15 parts by weight of an isocyanate  
crosslinking agent. The pressure-sensitive adhesive sheet  
had a tackiness of 1.0 N/25-mm as determined in the same manner  
as in Example 19 and had a surface resistivity (ASTM D-257)  
10 of  $1 \times 10^2 \Omega$  on the antistatic-treated side  
(aluminium-deposited side).

EXAMPLE 21

A cleaning sheet was prepared by evaporating aluminium  
as an electrically conductive substance to a thickness of 1000  
15 angstroms onto one side of a polyester film (substrate) 0.05  
mm thick; and forming a layer of a foam 0.8 mm thick on the  
other side. The foam layer was composed of a rubber latex and  
was formed by mechanical foaming. The cleaning sheet had a  
surface resistivity (ASTM D-257) of  $1 \times 10^2 \Omega$  on the  
20 antistatic-treated side (aluminium-deposited side).

COMPARATIVE EXAMPLE 11

A cleaning pressure-sensitive adhesive sheet was  
prepared in the same manner as in Example 19, except that the  
substrate was not subjected to antistatic treatment. The  
25 cleaning pressure-sensitive adhesive sheet had a tackiness of

1.4 N/25-mm as determined in the same manner as in Example 19 and had a surface resistivity (ASTM D-257) of  $6 \times 10^{16} \Omega$  on the side where the pressure-sensitive adhesive was not applied.

5 COMPARATIVE EXAMPLE 12

A cleaning pressure-sensitive adhesive sheet was prepared in the same manner as in Example 20, except that the substrate was not subjected to antistatic treatment (aluminium deposition). The cleaning pressure-sensitive adhesive sheet had a tackiness of 1.0 N/25-mm as determined in the same manner as in Example 19 and had a surface resistivity (ASTM D-257) of  $3 \times 10^{15} \Omega$  on the side where the pressure-sensitive adhesive was not applied.

10 COMPARATIVE EXAMPLE 13

A cleaning pressure-sensitive adhesive sheet was prepared in the same manner as in Example 21, except that the substrate was not subjected to antistatic treatment (aluminium deposition). The cleaning sheet had a surface resistivity of  $3 \times 10^{15} \Omega$  on the side where the foam layer was not formed.

15 Evaluation Test

Each of the cleaning sheets obtained according to Examples 19 to 21 and Comparative Examples 11 to 13 was evenly stuck to and peeled off from the back of a screen printing plate, 20 which had been used a predetermined number of times and carried

a paste (a fluorescent paste for use in the manufacture of a plasma display panel) turned about the back to thereby clean the screen printing plate. As a result, when each of the cleaning sheets according to Examples 19 to 21 was used, no bleeding occurred in a printed matter printed after cleaning and no malfunction occurred due to static electricity. In contrast, when each of the cleaning sheets according to comparative Examples 11 to 13 was used, droplets of the paste on the screen printing plate spread around, and an operator felt electrical shock when he/she touched the sheet during cleaning operation, although no bleeding occurred in a printed matter printed after cleaning.

## CLAIMS

1. A pressure-sensitive adhesive sheet for removal of  
a solvent-containing substance, the sheet comprising a  
5 substrate and a pressure sensitive adhesive layer formed at  
least on one side of the substrate, wherein the pressure  
sensitive adhesive layer adsorbs 20 g/m<sup>2</sup> or more of a solvent  
contained in the substance to be removed when the  
pressure-sensitive adhesive sheet is immersed in the solvent  
10 for 3 minutes.

2. A pressure-sensitive adhesive sheet for removal of  
a solvent-containing substance, the sheet comprising a  
substrate and a pressure sensitive adhesive layer formed at  
least on one side of the substrate, wherein the  
pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of  
15 a solvent contained in the substance to be removed when the  
pressure-sensitive adhesive sheet is immersed in the solvent  
for 1 second, and wherein the pressure-sensitive adhesive  
sheet after absorbing 5 g/m<sup>2</sup> of the solvent has a tackiness  
20 of 1 cN/25-mm or more as determined by a method in conformity  
with Japanese Industrial Standards (JIS) Z 0237.

3. A pressure-sensitive adhesive sheet for removal of  
a solvent-containing substance, the sheet comprising a  
substrate and a pressure sensitive adhesive layer formed at  
25 least on one side of the substrate, wherein the

pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and wherein no stain is observed in a stainless steel plate (a SUS 430BA plate) by visual inspection when the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of the solvent is stuck to the stainless steel plate by a reciprocating motion of a 2-kg rubber roller and is peeled off from the stainless steel plate.

10        4. The pressure-sensitive adhesive sheet for removal of a solvent-containing substance according to claim 3, wherein a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer comprises such components alone that are insoluble in a solvent contained in the substance to be removed.

15        5. A pressure-sensitive adhesive sheet for removal of a solvent-containing substance, the sheet comprising a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate, wherein a difference  $\Delta\delta$  between the solubility parameter (SP)  $\delta_1$  [ $(J/cm^3)^{1/2}$ ] of a pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer and the solubility parameter (SP)  $\delta_2$  [ $(J/cm^3)^{1/2}$ ] of a solvent contained in the solvent-containing substance to be removed falls within a range of  $\pm 4$  [ $(J/cm^3)^{1/2}$ ].

6. A pressure-sensitive adhesive sheet for removal of a solvent-containing substance, the sheet comprising a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate, wherein the pressure-sensitive adhesive contains fine particles.

7. The pressure-sensitive adhesive sheet for removal of a solvent-containing substance according to claim 6, wherein the fine particles have a mean particle size of from 0.01 to 10  $\mu\text{m}$ .

10 8. The pressure-sensitive adhesive sheet for removal of a solvent-containing substance according to any one of claims 1 to 7, wherein the pressure-sensitive adhesive layer before use has a tackiness of from 1 to 400 cN/25-mm as determined by a method in conformity with JIS Z 0237.

15 9. The pressure-sensitive adhesive sheet for removal of a solvent-containing substance according to any one of claims 1 to 8, wherein the pressure-sensitive adhesive sheet is for use in cleaning of a screen printing plate.

10. A method for removing a solvent-containing substance deposited on an article to be cleaned, the method comprising the step of using a pressure-sensitive adhesive sheet, the pressure-sensitive adhesive sheet comprising a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate, wherein the pressure sensitive adhesive layer adsorbs 20 g/ $\text{m}^2$  or more of a solvent

contained in the solvent-containing substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 3 minutes.

11. A method for removing a solvent-containing

- 5 substance deposited on an article to be cleaned, the method comprising the step of using a pressure-sensitive adhesive sheet, the pressure-sensitive adhesive sheet comprising a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate, wherein the
- 10 pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the solvent-containing substance to be removed when the pressure-sensitive adhesive sheet is immersed in the solvent for 1 second, and wherein the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of
- 15 the solvent has a tackiness of 1 cN/25-mm or more as determined by a method in conformity with JIS Z 0237.

12. A method for removing a solvent-containing

- substance deposited on an article to be cleaned, the method comprising the step of using a pressure-sensitive adhesive sheet, the pressure-sensitive adhesive sheet comprising a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate, wherein the pressure-sensitive adhesive layer absorbs 5 g/m<sup>2</sup> or more of a solvent contained in the solvent-containing substance to be removed when the pressure-sensitive adhesive sheet is

immersed in the solvent for 1 second, and wherein no stain is observed in a stainless steel plate(a SUS 430BA plate) by visual inspection when the pressure-sensitive adhesive sheet after absorbing 5 g/m<sup>2</sup> of the solvent is stuck to the stainless 5 steel plate by a reciprocating motion of a 2-kg rubber roller and is peeled off from the stainless steel plate.

13. A method for removing a solvent-containing substance deposited on an article to be cleaned by the use of a pressure-sensitive adhesive sheet, the pressure-sensitive adhesive sheet comprising a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate, the method comprising the steps of (a) determining the solubility parameter (SP)  $\delta_1$  [(J/cm<sup>3</sup>)<sup>1/2</sup>] of a pressure-sensitive adhesive constituting the 10 pressure-sensitive adhesive layer, (b) determining the solubility parameter (SP)  $\delta_2$  [(J/cm<sup>3</sup>)<sup>1/2</sup>] of a solvent contained in the solvent-containing substance to be removed, and (c) selecting such a pressure-sensitive adhesive sheet that a difference  $\Delta\delta$  between  $\delta_1$  and  $\delta_2$  falls within a range of  $\pm 4$  15 [(J/cm<sup>3</sup>)<sup>1/2</sup>] and removing the solvent-containing substance with the use of the selected pressure-sensitive adhesive 20 sheet.

14. The method for removing a solvent-containing substance according to claim 13, wherein, in Step (a), the 25 pressure-sensitive adhesive sheet is immersed respectively in

plural solvents having different solubility parameters (SPs) to thereby determine the degree of swelling or gel fraction of the pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer, and the solubility parameter (SP) of a solvent, in which the pressure-sensitive adhesive exhibits the maximum degree of swelling or the minimum gel fraction, is defined as the solubility parameter (SP)  $\delta_1 [(J/cm^3)^{1/2}]$  of the pressure-sensitive adhesive constituting the pressure-sensitive adhesive layer of the pressure-sensitive adhesive sheet.

15. A method for removing a solvent-containing substance deposited on an article to be cleaned, the method comprising the step of using a pressure-sensitive adhesive sheet, the pressure-sensitive adhesive sheet comprising a substrate and a pressure-sensitive adhesive layer formed at least on one side of the substrate, wherein the pressure-sensitive adhesive layer contains fine particles.

20. A sheet for removal of a solvent-containing substance, the sheet comprising a substrate and a pressure-sensitive adhesive layer or a foam layer formed at least on one side of the substrate, wherein the sheet has been subjected to antistatic treatment.

25. The sheet for removal of a solvent-containing substance according to claim 16, wherein at least one of both sides of the sheet has a surface resistivity of  $10^{13} \Omega$  or less.

18. The sheet for removal of a solvent-containing substance according to claim 16 or 17, wherein the sheet is for use in cleaning of a screen printing plate.

19. A method for removing a solvent-containing substance deposited on an article to be cleaned, the method comprising the step of using a sheet, the sheet comprising a substrate and a pressure-sensitive adhesive layer or a foam layer formed at least on one side of the substrate, wherein the sheet has been subjected to antistatic treatment.

# BIRCH, STEWART, KOLASCH & BIRCH, LLP

## COMBINED DECLARATION AND POWER OF ATTORNEY FOR PATENT AND DESIGN APPLICATIONS

PLEASE NOTE:  
YOU MUST  
COMPLETE THE  
FOLLOWING:

Insert Title:

As a below named inventor, I hereby declare that: my residence, post office address and citizenship are as stated next to my name; that I verily believe that I am the original, first and sole inventor (if only one inventor is named below) or an original, first and joint inventor (if plural inventors are named below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

► PRESSURE SENSITIVE ADHESIVE SHEETS FOR REMOVAL OF  
SOLVENT-CONTAINING SUBSTANCES

Fill in Appropriate  
Information -  
For Use Without  
Specification  
Attached:

the specification of which is attached hereto. If not attached hereto,

the specification was filed on \_\_\_\_\_ as  
United States Application Number \_\_\_\_\_; and /or

the specification was filed on June 13, 2000 as PCT  
International Application Number PCT/JP00/03812; and was  
amended under PCT Article 19 on \_\_\_\_\_ (if applicable)

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in Title 37, Code of Federal Regulations, §1.56.

I do not know and do not believe the same was ever known or used in the United States of America before my or our invention thereof, or patented or described in any printed publication in any country before my or our invention thereof or more than one year prior to this application, that the same was not in public use or on sale in the United States of America more than one year prior to this application, that the invention has not been patented or made the subject of an inventor's certificate issued before the date of this application in any country foreign to the United States of America on an application filed by me or my legal representatives or assigns more than twelve months (six months for designs) prior to this application, and that no application for patent or inventor's certificate on this invention has been filed in any country foreign to the United States of America prior to this application by me or my legal representatives or assigns, except as follows.

I hereby claim foreign priority benefit under Title 35, United States Code, §119 (a)-(d) of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s)	JAPAN	January 19, 2000	Priority	Claimed
9737/2000 (Number)	(Country)	(Month/Day/Year Filed)	<input checked="" type="checkbox"/>	<input type="checkbox"/>
153867/2000 (Number)	JAPAN (Country)	May 24, 2000 (Month/Day/Year Filed)	<input checked="" type="checkbox"/>	<input type="checkbox"/>
(Number)	(Country)	(Month/Day/Year Filed)	<input type="checkbox"/>	<input type="checkbox"/>
(Number)	(Country)	(Month/Day/Year Filed)	<input type="checkbox"/>	<input type="checkbox"/>
(Number)	(Country)	(Month/Day/Year Filed)	<input type="checkbox"/>	<input type="checkbox"/>
(Number)	(Country)	(Month/Day/Year Filed)	<input type="checkbox"/>	<input type="checkbox"/>

I hereby claim the benefit under Title 35, United States Code, §119(e) of any United States provisional application(s) listed below.

(Application Number)	(Filing Date)
(Application Number)	(Filing Date)

All Foreign Applications, if any, for any Patent or Inventor's Certificate Filed More Than 12 Months (6 Months for Designs) Prior To The Filing Date of This Application:

Country	Application No.	Date of Filing (Month/Day/Year)

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose information which is material to patentability as defined in Title 37, Code of Federal Regulations, §1.56 which became available between the filing date of the prior application and the national or PCT international filing date of this application:

(Application Number)	(Filing Date)	(Status - patented, pending, abandoned)
(Application Number)	(Filing Date)	(Status - patented, pending, abandoned)

ATTORNEY DOCKET NO.  
3213-0146P

I hereby appoint the following attorneys to prosecute this application and/or an international application based on this application and to transact all business in the Patent and Trademark Office connected therewith and in connection with the resulting patent based on instructions received from the entity who first sent the application papers to the attorneys identified below, unless the inventor(s) or assignee provides said attorneys with a written notice to the contrary:

Terrell C. Birch	(Reg. No. 19,382)	Raymond C. Stewart	(Reg. No. 21,066)
Joseph A. Kolasch	(Reg. No. 32,463)	James M. Slattery	(Reg. No. 28,380)
Bernard L. Sweeney	(Reg. No. 24,448)	Michael K. Mutter	(Reg. No. 29,680)
Charles Gorenstein	(Reg. No. 29,271)	Gerald M. Murphy, Jr.	(Reg. No. 28,927)
Leonard R. Svensson	(Reg. No. 30,330)	Terry L. Clark	(Reg. No. 32,644)
Andrew D. Meikle	(Reg. No. 32,868)	Marc S. Weiner	(Reg. No. 32,181)
Joe McKinney Muncy	(Reg. No. 32,334)	Donald J. Daley	(Reg. No. 34,313)
C. Joseph Faraci	(Reg. No. 32,350)		

Send Correspondence to:
